THE LANCET

Journal of British and Foreign Medicine, Surgery, Obstetrics, Physiology, Chemistry, Pharmacology, Public Health, and News.

227

IN TWO VOLUMES ANNUALLY

VOL. CCXI.

VOL. II. FOR 1926.

ONE HUNDRED AND FOURTH YEAR.

EDITED BY

SIR SQUIRE SPRIGGE, M.A., M.D. CANTAB., F.R.C.S. ENG.,

AND

EGBERT MORLAND, B.Sc., M.B. LOND., M.D. BERNE.

LONDON
PUBLISHED BY THE PROPRIETORS, THE LANCET LIMITED, NO. 423, STRAND, AND NO. 1, BEDFORD STREET, STRAND, IN THE COUNTY OF LONDON, AND PRINTED BY HAZELL, WATSON & VINEY, LD., 52, LONG ACRE, W.C. 2.
MCMXXVI

INDEX TO VOLUME II., 1926.

☞ *Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c, &c., and that regional headings are more frequently used than pathological Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies All Universities are indexed under the word University (A.) = Annotation, (C) = Correspondence, (N I) = New Inventions, (L A) = Leading Article, (M L) = Medico-legal, (M T T) = Modern Technique in Treatment, (O) = Obituary (P.I) = Parliamentary Intelligence, (R.) = Review, and (R and A R) = Reports and Analytical Records*

A Concordance of page numbers and dates of Issue will be found at the end of the Index.

A

ON

CHOLECYSTOGRAPHY.

Delivered before the Royal College of Surgeons of England

BY STANFORD CADE, F R C S ENG,
ASSISTANT SURGEON, WESTMINSTER HOSPITAL.

RADIOLOGICAL diagnosis of the condition of the biliary tract has made a distinct advance by the development of cholecystography Ewart A Graham published in 1924 the preliminary report[1] of the method known as Graham's test, by which a radiogram of the gall-bladder is obtained after intravenous injection of certain chemical substances Following the investigation of the hepatic function by its power of excreting certain dyes, first introduced by Rowntree, Hurwitz, and Bloomfield[2] in 1923, Graham conceived and carried out a systematic series of experiments for the production of hepatitis and cholecystitis, this led to the investigation of the gall-bladder by means of certain salts which are taken up from the blood stream by the liver and excreted in the bile, and which are opaque to the X rays when concentrated In a series of papers published[3 4 5] in 1924 and 1925 Graham and his collaborators have gradually improved the technique of this method of investigation The substance employed is one of the halogen elements linked with phenolphthalein Iodine and bromine were found to be the most suitable halogens, and a comparison of the two was worked out by Whitaker and Milliken[6] These workers, as well as Carman,[7] Sherwood Moore, and many others,[8 9] have put the method to clinical tests and correlated their results The method has been eagerly tried by many clinicians, and papers by Cohen and Roberts[10] and by Wilkie and Illingworth[11] have been published recently

In my experience the use of sodium tetraiodophenolphthalein gives the better results The radiograms are much more distinct than those with the bromine salt The toxicity is so low that, if the dosage is carefully regulated and the patient suitably prepared, no unpleasant symptoms result, with very few exceptions Intravenous administration is vastly superior to the oral method if a good shadow is desired

TECHNIQUE

The preparation of the patient is important The stomach must be empty and the alimentary canal as free from gas as possible No food is to be given during the period the radiograms are taken Protein is omitted from the last meal on the eve of the injection 40 gr of sodium bicarbonate are given two-hourly during the day A maximum dose of 4 5 g of sodium tetraiodophenolphthalein dissolved in 40 c cm of double distilled water is injected intravenously, the solution must be warm and injected very slowly No ill-effects have been noticed from a single injection, but Graham[3] and Carman[7] advocate the administration of two equal half doses at a half hour's interval The greatest possible care must be taken that the solution is given intravenously, the escape of even the smallest quantity into the subcutaneous tissue produces cellulitis and necrosis Skiagrams are taken 4, 8, 24, and, if necessary, 30 hours later

Normal Biliary System

In cases where the biliary system is normal and the gall-bladder healthy a shadow is obtained three hours after the injection of the dye The density of the shadow will vary with the softness or hardness of the tube and the length of exposure With a correct radiological technique uniform results are obtained The size of the shadow is always larger than the actual gall-bladder It is largest four hours after inject and gradually diminishes in size of gall-bladder shadow is generally pyriform with the base downwards, less frequently it is ovoid and rarely spherical

Position of the Gall-bladder.

When full the fundus reaches, as a rule, the transverse process of the third lumbar vertebra, its upper extremity extending to the transverse process of the first lumbar or just below it The long axis is directed downwards and slightly outwards, parallel with the psoas muscle In narrow-chested individuals the position may be vertical, in cases with a wide thoracic angle it is more horizontal; the relation of the shadow to the twelfth rib is variable, most commonly it is well below it; not infrequently it is only a short distance from it, and at times at the level of the twelfth rib A shadow above the twelfth rib is an indication of abnormality most commonly due to adhesions, the high-situated shadows are, as a rule, more spherical and smaller than the low ones, one can regard the small, round shadow situated between the eleventh and twelfth ribs, well away from the transverse processes, as an indication of cholecystic disease

The gradual diminution of the shadow in the course of 24 hours is evidence of the normal elasticity of the muscular coat In a fasting individual this diminution in size is gradual and regular, and takes place in all directions, the shadow becoming shorter and narrower.

It has been observed that the density of the cholecystogram increases from the fifth to the tenth or twelfth hour, and then gradually diminishes This variation in density is an important feature, it indicates a normal and healthy mucosa and is a proof of the power the gall-bladder possesses to concentrate bile; the power of concentration is a normal function of the biliary vesicle and depends on the state of the mucosa Rous and McMaster[12] have shown that the normal gall-bladder concentrates the bile which passes through it sometimes as much as ten times, and Boyd,[13] in examining the gall-bladder by means of a dissecting microscope, described in detail the appearance of the mucosa so admirably suitable for absorption The gradually increasing density of the cholecystogram is in entire agreement with the conclusions drawn from those observations. The function of the gall-bladder is reduced to that of a mere reservoir only in cases where the mucosa has been changed by disease into a thin atrophied lining In these cases there is no variation in the density of the successive shadows

The dye as excreted by the liver is not sufficiently opaque to cast a shadow[14] The ducts do not possess the property of concentrating the bile; on the contrary, it has been shown that they dilute the bile with a thin secretion of their own· this secretion, which is colourless and devoid of cholates, is the so-called "white bile" found in certain pathological conditions Consequently, in cases of common duct obstruction, owing to lack of concentration, no shadow is obtained, although the gall-bladder is present and the cystic duct patent

Rate of Emptying

The difficulty of ascertaining the rate of bile flow from the gall-bladder in normal individuals and animals has given rise to contradictory statements In observations on biliary fistulas one is dealing with an abnormal condition, this criticism applies even more forcibly to observations under anæsthesia; from clinical studies with the duodenal tube different observers have arrived at different conclusions The visualised human gall-bladder casts an opaque shadow which, photographed at periodical intervals, gives a true picture of the variations in size during the period of opacity The activity of the gall-bladder varies with intake of food In fasting individuals there is a slow and progressive emptying of the biliary vesicle which is fairly constant The size of the shadow becomes gradually smaller and is about one-third of its original 30 hours This gradual emptying is a constant n in all normal gall-bladders observed. In t the surface areas of the

SUGGESTIONS FOR EFFECTIVE

PLURIGLANDULAR OPOTHERAPY

DIGLOBIN → **ANÆMIA**

Spleen Extract and Epiphyseal Bone Marrow.

jaundice is no contra-indication for the administration of sodium tetraiodophenolphthalein.

I have investigated cases of common duct obstruction due to neoplasm of the pancreas with large easily palpable distended gall-bladders, and cases of calculus obstruction with shrunken atrophied biliary vesicles; in none was a shadow obtained. The conclusions drawn from the study of these cases controlled by operation or autopsy are that in obstruction of the common duct the gall-bladder function is abolished and its power of concentrating bile is diminished.

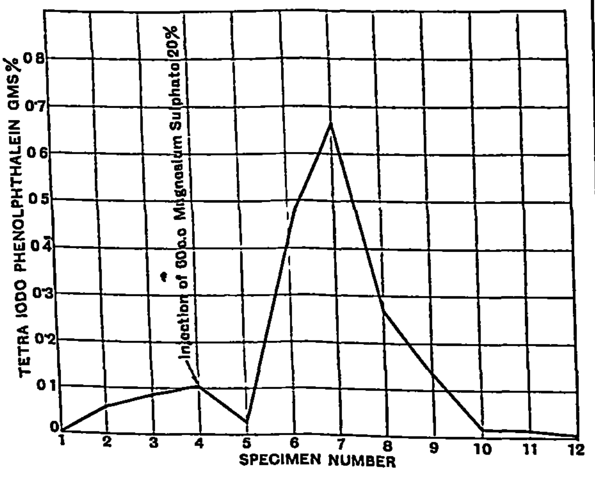
GALL-STONES

The opacity of gall-stones to the X rays depends on their chemical composition. Pure cholesterin stones are so transparent that no shadow is obtained; calculi containing calcium are opaque, and the density of the shadow is in direct proportion with the amount of calcium salts present. Ringed shadows are very typical. The appearances of cholecystograms in cases of lithiasis without cystic duct obstruction depend upon two factors—the degree of cholecystitis and the number of stones. If the stones are so numerous as to fill the gall-bladder, or if there is marked cholecystitis, no cholecystogram is obtained. With fewer stones the shadow is of mottled appearance, and the stones become more opaque as the density of the shadow is increased. The mottling of the shadows is definite evidence of gall-stones. The usefulness of the method lies in the fact that gall-stones which are invisible in a preliminary radiogram, when immersed in bile containing the dye are outlined as negative shadows. Also some calculi, by absorbing the dye in sufficient amount, become visible in the skiagrams. Further, it is a means of differentiating gall-stones from shadows cast by glands, stercoliths, renal calculi, and phleboliths.

CHRONIC NON-CALCULOUS CHOLECYSTITIS

This condition was first described by Keen in 1883, and since by numerous pathologists and surgeons. Clinically it may resemble gall-stone disease so closely as to merit the name pseudo-cholelithiasis, or the main burden of the symptoms may, on the other hand, be extravesicular. These extravesicular symptoms, predominant in the patient's account of his illness, consist in gastric or intestinal disturbance, deterioration of general health, repeated migraine, and signs of toxæmia, which accounts for the frequent mistaken diagnosis. The vesicular symptoms are transient and obscured in the patient's mind by the more obtrusive general discomfort; they are present, none the less, and will be found if looked for.

FIG. 2



The essential histological picture is the gradual replacement of all the layers of the gall-bladder wall by inflammatory fibrosis. The changes vary in degree according to the duration of disease. In the early stages there is round-cell infiltration of the submucosa, some shedding of the epithelium, formation of small diverticula containing bile grit, and a slight degeneration of the muscle; later on the mucosa degenerates and stains feebly, the fibrosis of the muscular wall is increased, and the subperitoneal stratum is beginning to be invaded with fat. In the late stages the columnar epithelium is replaced by a layer of flattened cells, or the mucosa may be absent altogether; the wall is thickened and no elastic and muscular tissue can be distinguished; the fat under the peritoneum is greatly increased.

The diagnosis, although not obvious, can be arrived at in combining careful clinical examination with cholecystography and the Meltzer-Lyon test. Cholecystographic findings are as follows. When the mucosa is grossly involved no opaque shadow is obtained. In lesser degrees the shadow is faint throughout; it does not vary in intensity and only slightly in size, and it conveys the information that the mucosa is incapable of concentrating the dye and that the elasticity of the viscus is lost—such a finding is a clear indication for cholecystectomy. In lesser degrees of disease the shadow is faint, and the rate of emptying is greatly diminished. This slow emptying, so apparent in consecutive cholecystograms, means biliary stasis; and the stagnation of bile is responsible for the symptoms produced. The importance of cholecystography in these cases lies not only in the aid in diagnosis but in the information obtained in connexion with the results of non-operative treatment and the progress of the case. The whole investigation can be done on out-patients; hospitalisation is preferable, but not essential. The following is the routine: a careful history of the case is taken, a preliminary radiogram obtained, after suitable preparation cholecystography by the intravenous method is done: if there is evidence of early chronic non-calculous cholecystitis the patient is given 5 g. of magnesium sulphate and 2 g. of De Witte's peptone, half an hour before breakfast and half an hour before dinner. This should not be given if there is obstruction in the cystic duct, as biliary colic may ensue.

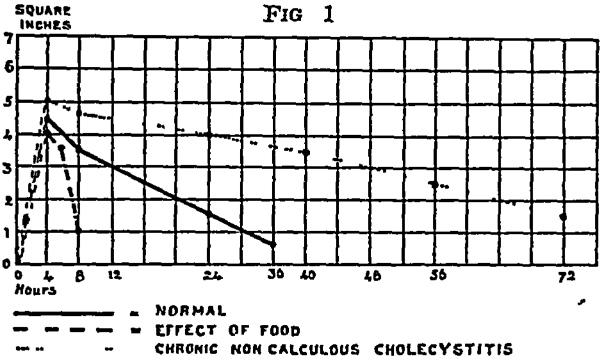
Treatment is continued for 10 or 14 days, and is followed by a second cholecystography, which shows if drainage has been efficient or not. If successful the rate of emptying is found to be increased and the shadows obtained approach the normal; if the picture remains unaltered it is obvious that the non-surgical drainage by magnesium sulphate-peptone is of no benefit and operation is indicated.[27] By this method a few cases of early cholecystitis can be rationally treated by medical means and their progress controlled. Other abnormalities observed relate to the implication of the gall-bladder in adhesions, to changes due to pericholecystitis. As previously mentioned, they can be summarised as follows: a shadow high situated between eleventh and twelfth ribs spherical in outline and of poor intensity.

In examining cases which previously had cholecystotomy performed it was found that none gave a normal opacity; in some no shadow was obtained showing loss of function of the viscus, subsequently proved by operation; in others very poor shadows were obtained. Without entering into the consideration of the value of cholecystostomy as compared to cholecystectomy, and admitting freely that both operations have their indications and their uses, cholecystography gives important information as to the functional capacity of gall-bladders previously drained. It appears from the preliminary investigation that the recovery of function after cholecystostomy occurs only in cases of lithiasis with very little cholecystitis. When drainage was chosen instead of removal owing to operative difficulties caused either by the anatomical or the pathological condition at the time of operation the recovery of function is very rarely established and sooner or later further trouble results. To quote Sir John Bland-Sutton: "A gall-bladder that has been subjected to a cholecystotomy is a liability rather than an asset."[28]

and plotting out the figures according to the time elapsed since injection a graphic representation of the rate of emptying is obtained The superimposed curves of over 25 normal graphic representations is taken as the average rate of emptying of a normal gall-bladder when fasting (Fig 1)

The effect of food was studied, and it was noticed that water, milk, tea have very little influence on the rate of emptying Solid food, specially fat, produces a rapid diminution of the size of the gall-bladder shadow; the graph obtained under these conditions shows a sharp fall in the curve Moreover, if the emptying is complete no further shadow is obtained, indicating that the intake of food is followed not only by emptying of the gall-bladder, but by increased activity of the liver and relaxation of the sphincter of Oddi, as most of the bile containing the dye is passed straight into the duodenum It was also noticed that in two cases of duodenal ulcer the rate of emptying was more rapid, this is interesting in view of the remark recently made by Charles Mayo that "Nature has provided us in the gall-bladder with a natural soda fountain, very useful in hyperacidity"

FIG 1



CHOLECYSTOGRAMS IN CONJUNCTION WITH MELTZER-LYON TEST

Doyon [15] in 1893 paved the way for the Meltzer-Lyon test in showing that the contraction of the muscular coat of the gall-bladder was dependent on its innervation by the great splanchnic nerve, and that the relaxation of the sphincter of Oddi was under the influence of the vagus In 1917 S J Meltzer [16] observed that the application of 25 per cent magnesium sulphate solution to the duodenal mucosa was followed by gaping of the ampulla of Vater and a flow of bile Two years later Vincent Lyon [17] carried out Meltzer's experiment on the human subject and postulated the non-surgical drainage of the gall-bladder The emptying of the gall-bladder after the intraduodenal exhibition of magnesium sulphate, known as the Meltzer-Lyon test, has been criticised by Einhorn,[18] Auster and Crohn,[19] Diamond,[20] and a host of others [21] It was maintained that the flow of green bile (bile B) was due to the action of magnesium sulphate on the liver Numerous complicated and ingenious experiments were carried out to prove that the dark-coloured bile obtained in the Meltzer-Lyon test was not vesical but hepatic in origin Substances other than magnesium sulphate were found to produce the same effect Lyon himself failed to observe the contraction of the gall-bladder in the anæsthetised dog, and explained the failure by the fact that the reflex was "easily disturbed" [22] Bassler, Lucket, and Lutz [23] failed to see the contracting gall-bladder Gradually it came about that the gall-bladder was robbed by some authors of all power of contraction On perusal of the rapidly increasing literature on this subject [24] one cannot fail to be impressed by the importance attached to the Meltzer-Lyon phenomenon The combination of cholecystography with the Meltzer-Lyon test has the advantage that it is carried out without anæsthesia, without laparotomy, with very little disturbance of the reflex itself It gives photographic evidence of a reduction in size and alteration in position of the gall-bladder shadow And since non-surgical drainage of the gall-bladder with the appearance of a large amount of dark-coloured bile is accompanied by the alteration in shape and diminution in size of the cholecystogram, the bile obtained by the test must be vesical and not hepatic Further, the bile B thus obtained showed to contain a large amount of tetraiodophenolphthalein (Fig 2) Silverman and Melville [25] combined cholecystography with the Meltzer-Lyon test and arrived at the same conclusions

Chiray and Pavel [26] have analysed the various experiments, and conclude that the gall-bladder contractions exist, that they are of small amplitude *and long duration*, and therefore difficult to observe My own experiments on dogs have shown distinct contractions of the gall-bladder after application of magnesium sulphate to the duodenum I repeated the experiments in the presence of Dr de Souza, who observed the same result

In reviewing the various normal functions attributed to the gall-bladder cholecystography helps to transfer these functions from the realm of hypothesis to that of fact The gall-bladder acts as a reservoir and stores bile secreted in between meals The gall-bladder is contractile and expels its contents by waves of contractions of *slow amplitude accelerated by the* entrance of chyme into the duodenum The gall-bladder concentrates bile These various functions are deduced from the *appearance of the opaque* shadow its increase in density, its gradual disappearance when fasting, and its quick emptying after food or with the action of magnesium sulphate.

PATHOLOGICAL BILIARY SYSTEM.

Cholecystography as an aid to clinical diagnosis of disease of the biliary system requires no apology. Although the diagnosis of a number of cases presents no special difficulty, it is notorious that the characteristic symptom of biliary disease is the lack of definite characteristics, and the mimicking of gastric and duodenal symptoms is a fruitful source of errors in diagnosis Familiarity with normal cholecystographic appearances is obviously *essential for the detection* and correct interpretation of abnormal findings The absence of shadow or negative result is a sign of disease It has been *accepted by all who are familiar* with the method and has been proved time after time by operation

A stone in the cystic duct or in Hartman's pouch, or scarring of the duct, prevents the entrance of the dye into the gall-bladder and no shadow is obtained. The *information* derived *from* cholecystography in that type of lesion is illustrated by the following case

A lady, aged 73, was admitted under the care of Sir James Purves Stewart for an abdominal tumour and gastritis She had suffered from gastritis for 30 years, for the last two years there was progressive loss of weight, marked deterioration of general health, frequent bouts of vomiting, persistent constipation, and a constant dull ache on the right side of abdomen On examination a large, hard, solid tumour was felt in the right hypochondrium and right iliac fossa The tumour was at first thought to be renal but a pyelogram showed normal calyces and pelvis, it was then considered to be a colonic growth—a bismuth meal showed a normal alimentary canal I was asked to see the patient with view to cholecystography The radiograms, taken 4, 8, 24, and 36 hours after injection, showed no gall-bladder shadow, and in the second plate a circular ringed shadow with darker nucleus became apparent The diagnosis was gall-stones and cholecystitis with large Riedel's lobe At operation under regional anæsthesia I found a large Riedel's lobe covering a bilocular *gall-bladder adherent* to duodenum, stomach, colon, and omentum, the proximal loculus contained a large stone in Hartman's pouch, the *distal* loculus contained multiple stones, and communicated by perforation with an abscess in the adherent omentum *Cholecystectomy* was performed The patient made an uninterrupted recovery

Every case of obstruction of the cystic duct gave negative cholecystographic findings In cases with obstruction of the common duct from whatever cause no shadow of the gall-bladder is obtained Presence of symptoms followed intravenous injection; the symptoms occurred within one or two minutes after injection, and were as follows giddiness headache, nausea, vomiting sudden fall of blood pressure (the pulse at the wrist could not be felt for half to three-quarters of an hour), and acute abdominal pain The symptoms were very alarming, recovery was gradual but complete and both patients were fit to leave the hospital five hours later I have reason to believe that the toxic effect was partly due to a too rapid injection and partly to oxidation of the iodo compound The necessity of slow administration cannot be emphasised too strongly, the salt itself must be absolutely pure and as fresh as possible With these precautions and attention to the accuracy of the dose and preliminary preparation I consider the method as an absolutely safe procedure

Oral administration never gives as good results as the intravenous method, it gives also far less information as regards function of the gall-bladder, as the shadow appears much later lasts a shorter period and is never as dense as that obtained by the intravenous injection In my opinion oral administration presents definite inconvenience and it cannot be said to be safer The drug has to be given in solid form · as contact with hydrochloric acid produces a definite chemical reaction, it is customary to give it in capsules, enteric capsules have been tried and discarded owing to delay of solution, ordinary gelatin capsules often fail to liberate the dye and small masses of the drug can be watched under the fluoroscopic screen in their transit through the alimentary canal, the rate of absorption is extremely variable and, owing to the laxative action of the phenolphthalein, a good deal of the dye is lost, this accounts for the poor shadows obtained and the unstability of results A negative result after oral administration is therefore of no value, on the other hand, after intravenous injection is definite evidence of disease The loss of the salt by the bowel cannot be made good by giving a larger dose orally, as the stomach and intestine do not tolerate it and vomiting and diarrhœa result. this explains why the advocates of the oral method never exceed by the mouth the intravenous dose, and often give less The advantage of oral administration is simplicity, but for this method to be of full value it is necessary to give a substance which is rapidly absorbed by the intestine, is non-irritant to the mucosa, and non-toxic, so that a much larger dose than is necessary to produce a shadow could be given to allow for the loss by passage through the alimentary canal Sodium tetraiodophenolphthalein does not possess these properties, neither does strontium bromide advocated by some Italian clinicians Dr F D M Hocking however, is at present engaged in the preparation of a chemical compound which one hopes will fulfil the necessary desiderata for oral administration

Summary

Cholecystography is a new method of investigation of the biliary system based on the capability of the liver to excrete certain dyes opaque to the X rays

It is a means of studying the topographical anatomy of the gall-bladder in the living; it throws light on the physiology of the gall-bladder, on its activities under various conditions, and on its multiple functions In disease it provides additional information in late and in early stages It is a means of controlling the non-operative treatment of chronic cholecystitis

It is not meant to replace clinical diagnosis, but adds greatly to its accuracy It is to the biliary system what the opaque meal is to the alimentary canal, and pyelography to the urinary tract It has made rapid advances in a very brief period of time and has gained for itself, I believe, a permanent position amongst modern methods of investigating disease

In conclusion, I have much pleasure in expressing my obligation to all those who collaborated with me in this study To Dr W H Coldwell I am indebted for all the radiological and radiographic work, and for the willingness with which he placed at my disposal his entire department, his time and his skill To Mr Arthur Evans my thanks are due for his whole-hearted and encouraging interest in the method, his unstinted generosity in the matter of hospital beds, and for giving me the opportunity of investigating cases of biliary disease under his care In the John Burford Carlill laboratories the pathological work connected with this investigation was carried out by Dr Braxton Hicks who examined all specimens, human and animal, and the biochemical work was done by Dr Hocking, to both I am greatly indebted To Mr Price Thomas I wish to express my appreciation for the valuable assistance with the animal experiments and the clinical part of the work

An Address
ON THE
HEALTH OF PROFESSIONAL WOMEN.

Delivered to the London Association of the Medical Women's Federation on June 8th, 1926,

BY LETITIA FAIRFIELD, C B E, M D EDIN, D P H,
FORMERLY WOMAN MEDICAL DIRECTOR TO WOMEN'S ROYAL AIR FORCE.

MODERN social and economic developments have brought important changes in the lives of women which necessarily have involved profound effects on their health These results have been much discussed, and in the case of the *industrial* woman have been made the subject of intensive study from which she has derived substantial benefit The *professional* woman is much less accessible to observation, and the exact data which are a condition precedent to advance in hygiene and success in the prevention of disease are deplorably lacking With the exception of the comparative statistics furnished by the post office about its employees, and a few small inquiries conducted in training colleges, a paper on the Sickness Data of Elementary School Teachers in London, 1904–19, by Mr J Y Hart, B Sc (*Journal of the Royal Statistical Society*, 1922) stands almost alone as a detailed study I have therefore ventured to present some observations on the health of profes-

It can therefore be concluded that non-appearance of the shadow is definite indication of cholecystic disease Mottling is evidence of gall-stones Chronic cholecystitis gives definite abnormality in the cholecystogram Cholecystectomy is indicated when the function of the gall-bladder is impaired

Histological evidence of disease has been found in every case where the shadow was abnormal or absent The surgeon will have to learn to distinguish from the appearance of the gall-bladder on laparotomy the early signs of disease in the absence of stones I have removed 30 gall-bladders in the past ten months, my senior colleague, Mr Arthur Evans, has given me the opportunity of examining every gall-bladder operated on by him during the past year—a considerable number—and I gradually came to appreciate the macroscopical appearance in the early stages of cholecystic disease.

ANIMAL EXPERIMENTS

The object in performing animal experiments was to ascertain the following points (1) The path taken by the dye from the time it is injected into a vein till it reaches the gall-bladder (2) The way out from the gall-bladder (3) The effect of sodium tetraiodophenolphthalein in various doses on the tissues and organs of the body (4) The symptoms produced by an overdose (5) The effect produced on the gall-bladder of magnesium sulphate in the duodenum All experiments were carried out on healthy adult dogs

In injecting the dye into a vein of a limb the dye is introduced into the systemic circulation It is carried to the heart, whence to the lungs and back to the heart, and so into the arterial stream It is presumed, as phenolphthalein is excreted by the liver, that in the course of the passage from the hepatic arteries into the hepatic vein the liver cells separate from the blood the phenolphthalein and with it the combined iodine In fact the dye is found in the bile canaliculi and is carried down to the gall-bladder by the hepatic and cystic ducts To prove this it is necessary to show that no dye can be separated by the gall-bladder itself from the blood stream The following experiment was carried out Laparotomy was performed on a fasting dog the gall-bladder was found to be fully distended ; the peritoneum over the cystic duct was incised, and the duct isolated by carefully separating it from the cystic artery and veins The duct was then divided between two ligatures The abdomen was closed and the dog allowed to recover When well a maximum dose of sodium tetraiodophenolphthalein was given intravenously, seven hours after injection the abdomen was opened a second time, the gall-bladder was seen to be normal in every respect and its blood-supply unimpaired, the gall-bladder was removed and its contents tested chemically and spectroscopically for the presence of the dye with absolutely negative results, the reactions being capable of showing 0 00001 g of the dye A specimen of blood of the same animal taken at the same time showed on analysis presence of the dye, this shows that no dye has entered the gall-bladder and that the mucosa is incapable of separating it from the blood stream [14]

The next experiment was made with the object to find out if any dye is absorbed from the gall-bladder by its blood-vessels or lymphatics Laparotomy was performed The cystic duct was isolated as before and divided between two ligatures, avoiding injury to its vascular supply A measured quantity—namely, 2 5 c cm of the dye (0 281 g)—was injected into the gall-bladder with a fine hypodermic needle As it is known that the dye produces necrosis of tissue a small quantity only was given and this was well diluted The abdomen was closed The dog was X rayed two days later, but no shadow was obtained, probably owing to the minute quantity of the dye injected, seven days later the abdomen was reopened, the gall-bladder, which appeared normal, was aspirated and the contents analysed The iodine content of the specimen showed the recovery of 84 1 per cent of total salt injected, by weight 0 236 g The small discrepancy in the figures is fully accounted for by the fact that not all the contents of the gall-bladder were aspirated, and that some of the dye remained adherent to the syringe The mucosa of the gall-bladder appeared normal The conclusion drawn from this experiment is that no sodium tetraiodophenolphthalein is absorbed by the wall of the gall-bladder, and that its disappearance is due to the ejection through the cystic duct [29]

Gradually increasing doses of " tetraiodo " were given to dogs on several occasions It was found that doses up to 0 2 g per kilo of body-weight produced no toxic effect, and repeated injections of non-toxic doses at regular short intervals up to full dose had no apparent cumulative effects on the animals, but when killed fatty degeneration of the liver and nephric changes were found histologically A large overdose, 5 g, given to a dog weighing 8 kilos, was followed by an immediate fall of blood pressure, and death occurred within 25 minutes. A dose of 3 5 g given to a dog weighing 7 kilos resulted in death after 16 hours The following symptoms were observed weakness (animal could not sit), fall of blood pressure, diarrhœa, vomiting, and convulsions *Post-mortem* examination revealed intense congestion of the liver and kidneys, these viscera being almost black, the heart was dilated, the bladder contained some blood-stained urine, the lungs were bright pink Histologically the liver showed intense congestion, the intralobular veins were distended, the portal capillaries engorged, there were marked subcapsular hæmorrhages and areas of destruction of liver tissue were present in which were seen particles of pigment (probably altered blood), the kidneys were in a condition of glomerular nephritis, the brain was engorged and there was some fragmentation of cerebral cells

The experiments with intraduodenal application of magnesium sulphate, as previously related, showed definite contractions of the gall-bladder All the animal experiments were carried out at the Brown Institution, and I am indebted to the University of London for permission to work there, and to the Director, Dr F W Twort, for his courtesy and the facilities afforded

RECORD OF CASES AND ANALYSIS OF RESULTS

Table I shows the total number of cases examined, the relative numbers of positive and negative results, and the control by operation Table II gives the analysis of the various conditions which gave positive or negative results Amongst the 49 normal gall-bladders are included conditions such as gastric ulcer or appendicitis, where the appearance of the gall-bladder was subsequently judged to be normal at operation

TABLE I —*Cholecystographies*

(Total number of cases, 100)

Positive results	61	
Negative results	39	
Controlled by operation		55
" by autopsy		3
Not operated		42

TABLE II —*Total Number of Cases, 100*

Positive		Negative	
Normal gall bladder	49	Cystic duct obstruction	16
Mottled shadow	6	Chronic cholecystitis	9
Cholecystitis	4	After cholecystectomy	3
Catarrhal jaundice	1	After cholecystostomy	4
Acholuric jaundice	1	Malignant gall bladder	1
		" pancreas	5
		Chronic pancreatitis	1
	61		39

The vast majority of cases were done by the intravenous method, and showed no ill-effects after the injection The dose varied from 3 to 4 5 g, according to the weight of the patient The only symptoms noticed in a small number of cases were headache, flushing of the face, giddiness, transient nausea, within 10 or 15 minutes the patient had entirely recovered There is no evidence up till now of any remote consequences attributable to the use of the drug In two consecutive cases severe toxic some the necessity for prompt and prolonged rest from work was not recognised early enough.

GASTRO-INTESTINAL GROUP

The *gastro-intestinal* group is large (96 cases), but shows some encouraging features. First may be noted in all teachers a very remarkable improvement in the care of the teeth. In only nine instances did septic mouths appear to be even a contributory cause of ill health, and in but two of these was there any opposition to dental treatment. These figures would have seemed incredible 12 years ago and show both the encouraging possibilities of health education and the value of the advice. One notes an almost dramatic contrast with the foul teeth of the lower grade workers, such as school cleaners, whose slow recovery after trivial accidents and ailments is largely due to septic absorption from the mouth. Secondly, there is a diminution in constipation, certainly in *neglected* constipation, which again furnishes an agreeable contrast to the days of our professional youth. But too many women have still to admit difficulty in securing adequate evacuations, and there is much reason to think that the 25 cases of appendicitis and 31 of other bowel troubles are associated with this condition. Two defects of hygiene may be suspected. One, lack of physical exercise, is common in the older women, who rarely played games in girlhood and had no opportunity of keeping them up after leaving college. The result is a general lack of muscle tone, flabby abdominal walls, and sagging viscera. The tennis-playing, dancing young professional woman of to-day has a much better chance of an alert middle age. The second common error is one of dietetics. Nearly every constipated person one meets nowadays claims to be a large fruit-eater, but, like all of us, has difficulty in getting a good supply of fresh vegetables. It has escaped comment that a curious, and I believe unique, food situation has arisen in this country during the last few years. Thanks to commercial developments large amounts of fruit now enter into the diet of all except the very poorest, but vegetables, especially green vegetables, are actually more expensive and unobtainable than in former days. The question arises whether we have not got too much into the habit of thinking of diet as a matter of purely hypothetical vitamins. Are "fruit and vegetables" really interchangeable? Certainly all those primitive peoples whose freedom from appendicitis and bowel troubles we envy, eat largely of both. It is a pity that it does not pay anyone to teach the public to "eat more vegetables."

A further encouraging sign is that "chronic indigestion" and dyspepsia seem to be diminishing. Of the 27 gastric cases, some 10 were gastric or duodenal ulcer, but the remainder were acute and were usually first attacks. The typical pink-nosed old maid, with her bottle of bismuth mixture and flow of confidences about her stomach troubles, is happily on the way to extinction. In addition to the improvements in hygiene before noted—to which should be added the abolition of the corset—credit is due to the more energetic and thorough treatment adopted by the modern practitioner. During the past year six "martyrs to indigestion" have come to announce triumphantly that they have been relieved of their symptoms by operations for appendicitis, gall-stones, or omental band.

A most important element in securing good digestion and good health is money to buy proper food. Women never really liked dining on sardines and cheap pastry, but they must pretend that they do when they can afford nothing better. Improved pay and professional prospects probably mean more in the reduction of digestive troubles than any other single factor.

CANCER

Cancer was the chief cause of death among women teachers, 8 deaths out of 35 in 1925 being due to this cause. About 12 other cases are known to have been operated on in the last 18 months. The only point of interest which emerges is the old story of the need for earlier diagnosis and treatment. There have been some tragic cases of an ignorance of notorious symptoms almost incredible in educated women, but it is clear that the fault is not all on one side. There seems, as Dr. W. Fletcher Shaw points out in the *British Medical Journal* (June 19th, p. 1026), to be a great reluctance to examine in certain quarters. As it is impossible to be too explicit in popular education about cancer for fear of creating undue alarm, the only practicable course is to warn women in general terms to consult their doctors in certain events. If practitioners do not "play up," the bottom falls out of the whole preventive campaign, and the cancer death-rate will remain where it is.

The following table shows:

Teachers on Prolonged Sick Leave (1 to 12 months)
Total number, 13,748

1	Pulmonary disease (non tuberculous)—		
	Asthma	10	49
	Pneumonia and bronchitis, &c.	36	
	Miscellaneous	3	
2	Influenza		84
3	Nervous system—		
	Insanity	6	293
	Organic disease	47	
	Functional	240	
4	Rheumatism—		
	Rheumatic fever	21	37
	Chronic arthritis	16	
5	Infectious fevers		17
6	Ear nose and throat disease		68
7	Ophthalmic disease		12
8	Digestive system—		
	Appendicitis	25	96
	Gastric	27	
	Intestinal	31	
	Gall stones	13	
9	Circulatory system—		
	Cardiac	27	56
	Anæmia	9	
	Phlebitis and varicose veins	9	
	Arterio-sclerosis	11	
10	Diseases of women—		
	Hysterectomy	25	66
	Ovarian	9	
	Malposition, &c.	11	
	Menopause	11

	Mixed	36	
			900

DISEASES PECULIAR TO WOMEN

The *diseases of women* are of special importance, not only on their intrinsic merits but as the chief alleged reason for discrepancy between male and female sickness rates. The 25 hysterectomy and nine ovarian cysts were responsible for a heavy time loss in senior teachers, as they were all absent for over three months. This liability to tumour formation between the ages of 40 and 60 would seem to be a sex disability which cannot yet be brought within the scope of preventive medicine. With menstrual disabilities the condition is far otherwise. Only 10 were noted in this series of 900; it is true that they would be expected to show as short and recurrent rather than long absences, but such short absences if persistent would be included in this series. It is hoped to conduct an investigation this year into the precise amount of interference with work due to the menses in teachers and nurses. Tentative inquiries have shown that it is surprisingly small. London teachers are not a selected class, in that no teacher has ever been excluded from the service on this ground, but for many years strenuous efforts have been made to supervise the health of the girls in the London training colleges (and probably those elsewhere), so that any necessary treatment is secured while in college. Very few young teachers have left still suffering from dysmenorrhœa or menorrhagia. One finds that the coöperation of the family doctor is very much easier to secure than it was 12 years ago, and the usual maternal attitude that pain at the periods is an act of God with which it would be impious to interfere is gradually disappearing. Twenty years ago the late Dr. J. W. Ballantyne, of Edinburgh, told me with grim amusement of his struggles to get his colleagues to take an interest in the then unfashionable subject of the ailments of the expectant mother. "Some think they're too trivial and others too hopeless, and they all look on it as a woman's job to put up with them, anyhow"! It is possible that a similar attitude to menstrual disability has been responsible for much unnecessary suffering.

sional women, based on a series of 900 consecutive cases of teachers referred to the school medical officer on account of absence for over a month, and for sundry other reasons, and supplemented by a knowledge of the same staff at their daily occupation over a period of 12 years. The number of teachers concerned is 13,748. They make good material for study, as their conditions of pay are sufficient to procure reasonable amenities of life and the best of medical and dental attention, and they have derived, by reason of their profession, the maximum benefit from modern hygienic propaganda.

COMPARISON OF SICKNESS RATE IN WOMEN AND MEN

An important point about the health of women generally must be borne in mind throughout, and that is the higher sickness rate which women always show as compared with men living under approximately the same conditions. I have been unable to obtain comparative figures for recent years for London, but Mr. Hart points out that "sex is the most important factor in illness of teachers. The mean illness of men teachers was 4·6 days a year for the period 1904–19, and the corresponding figures for single women and married women are 8·2 and 9·3 respectively. Men are absent least and married women most."

The following table shows:

Average Day's Absence per annum, London, 1904–19

Age groups	Men	Single women	Married women	Age groups	Men	Single women	Married women
21–25	4·3	6·4	11·1	46–50	4·0	10·9	9·7
26–30	4·1	6·0	8·5	51–55	5·5	15·1	11·7
31–35	2·8	8·6	7·1	56–60	5·8	10·4	13·1
36–40	2·8	8·7	8·2	61–65	9·2	19·1	19·6
41–45	3·5	9·1	9·0				

This fact is the more remarkable as the death-rate of men and women shows a disparity in exactly the opposite direction. As Newsholme points out ("Vital Statistics," p. 205), the death-rates at all ages except 10–15 are higher in the male. This discrepancy is most marked both in England and the United States at the very ages, 45 to 65, when the sickness rate is most against the female.

The London rates for death and permanent invaliding show the same peculiarity. The death-rate of female teachers (1925) was 0·25 per cent., as against the male rate of 0·44 per cent., while the permanent disablement rate was 0·40 per cent. for females and 0·27 per cent. for males.

It would appear that in some paradoxical way women save themselves from death by becoming ill! But however gratifying the comparatively lower death-rate is to them, the higher morbidity rate is a nuisance to their employers, and it will be very important to note whether any part of it is due to remediable causes and could be diminished by improved conditions of life. The difference affects *every* disease, however, when short absences are counted, and would appear to be partly due to inferior resistance.

ANÆMIA AND DEBILITY

Anæmia and debility figures prominently in all certificates covering short absences, but in only 1 per cent. of 900 serious cases was it impossible on investigation to find any more definite cause. It is three times as common as among men teachers. The vague "unfitness" thus described interferes considerably with the efficiency of women's work. Lack of exercise, fresh air, and sunshine are common causes in young town-dwellers, but another common cause of debility is too long a journey to work. Some women stand long daily travelling very badly, and improve greatly if they live near their work, and get what fresh air they can at the week-ends.

Diet gets less attention than it deserves in conditions of obscure ill-health. "Intelligent omnivorousness with no fuss" has been described as the ideal, but where loss of vitality is accompanied by poor nutrition it is worth while inquiring into minutiæ. I have found that a very important factor in the health of young women is a *hot*, fairly substantial midday meal. Many teachers now employ a cook to prepare a good dinner in their sitting-room, and office workers are fortunate if they can find a club where similar provision is made. Food in the big multiple shops is a great snare; it is apt to be overcooked and much less nourishing than it seems. Observation should always be kept for the "no-breakfast faddist," and the woman with food phobias retained from childhood who may be starving in the midst of plenty. In investigating cases of malnutrition among the children in a good class school I found that 5 out of 13 cases were cherishing food fads under the sympathetic eye of foolish relatives, and such whims sometimes persist throughout life. By increasing attention to such details of hygiene a real improvement has been and is still being obtained in the health of the younger women.

CARDIAC DISEASE

Cardiac disease furnished 27 cases (3 per cent.). It was the most important single cause of invaliding permanently out of the service in 1925. These serious cases were of mixed origin—septic, rheumatic, and influenzal—and present no remarkable clinical features. There were many opportunities of noting how very reluctant patients are to obey their medical attendants' injunctions to rest in the early stages. A striking example of the value of this was seen in the first half of 1925 when I had a series of about 40 cases of "cardiac debility" due to influenza. All were away from one to six months, and practically all cleared up entirely. On the other hand, I am constantly seeing seriously damaged hearts whose initial failure dates from neglected attacks of influenza.

Because of its pulmonary, as well as its cardiac, complications *influenza* is a great foe of the woman who has to leave her home daily. The temptation to go out on a chill winter morning when "it may be only a cold" is very great, and puts the worker at a disadvantage with her domestic sister. Influenza is a most serious school disease, and one would like to see preventive inoculation tried in the schools on a large scale.

Pulmonary diseases constitute 49 cases out of the 900; 36 were cases of bronchitis or pneumonia, mostly in elderly teachers. Chronic bronchitis is seen most often in stout, flabby women who have lived sedentary lives, and it is hoped that a more active younger generation will escape this most troublesome complaint, which is a serious source of inefficiency from 55 onwards.

Laryngitis is responsible for many prolonged absences, and may be considered as an occupational disease of teachers. Noisy, dusty, and draughty schools play an important part in its causation, and suggest an obvious method of prevention. The common cause of former days—bad voice production—is now comparatively rare, as the subject is well taught in college. Excessive cigarette-smoking is a factor sometimes overlooked. Great benefit has followed to some of the cases in this series from removal of septic tonsils even after the age of 50.

The 16 *exophthalmic goitre* cases call for a special note, as this is a particularly serious disease in teachers. The medical advisers to this education authority have for many years paid special attention to hyperthyroidism, and have regarded definite signs of Graves's disease as a bar to entering the teaching profession. The strain of examination, and even more of work in the class-room, has an inimical effect on the course of the disease, and the temperamental instability which is a feature of hyperthyroidism is peculiarly unfortunate in a teacher. Of my 16 cases one has died, one has left the service gravely ill, five have developed serious nervous instability, though the symptoms have improved, five are still seriously ill, and only four have done well. In less to be pitied—and certainly pities herself less—than some of these neurotics, whose wretchedness does not end with themselves One person can blight the lives of 60 children for a year and spread misery among her relatives and colleagues Yet both the *cure* and *prevention* of the neuroses are on a far less satisfactory basis than those of physical ailments Indeed in certain quarters an attempt to apply any other remedy than "rest and change of scene" is regarded as a species of black magic

A preliminary difficulty in dealing with neurotic patients is that the cause is often not recognised by the patient herself I have been very much struck by the fact that in all this series the severity of the breakdown was in inverse ratio to the alleged cause Where the teacher had collapsed as a result of some disaster (even the loss of a widow's only child, or a daughter seeing a beloved father killed before her eyes) she is back at work within a month—shaken, but able and anxious to carry on The only exception is an unhappy love affair Where the "cause" is vague or trivial, the prognosis is much more doubtful.

OVERWORK

Overwork is one of the commonest reasons for breakdown alleged by teachers or their doctors—often where the patient cannot by any stretch of imagination be held to be overworking The fatigue due to genuine overwork clears up rapidly with rest under good hygienic conditions, and does not entail absence of more than a few days or at most a few weeks I have searched energetically but cannot remember seeing a single case in training college, schools, or in the Services during the war of *serious* breakdown due to this cause Recently I have seen three women with severe neuroses who had in fact been working very hard All denied having worries or that they knew of any other possible cause for their illness Ultimately the first admitted that she had been reluctantly forced into teaching by a domineering mother, and was hankering after the occupation once followed by her father, and the second confessed that she had recently been sent from a school she loved to one she hated, "the work would have been nothing if I'd liked it" The third was seeking distraction from an unhappy love affair It is significant that I have never known a girl break down permanently in the preliminary stages of the teaching profession who had not already desired to give up teaching, usually for reasons financial or amorous

It will be found that what is called overwork is usually too *monotonous* work, or lack of recreation and emotional outlet Often this is not the teacher's own fault, as the single women sometimes find that relatives make enormous claims on their time and money, without any of the compensations accruing to the married man One lady had had upkeep of children imposed on her which would leave her without a spare penny for ten years The entire burden of elderly parents is a common factor in these cases Sometimes temperament rather than circumstance is to blame and a woman may be suffering from a misunderstanding of her own needs As one depressed lady in her late thirties remarked, she had been wasting her life at evening classes when she should have been learning to fox-trot Teachers as well as children must know how to play if they are to keep healthy Fortunately more attention is being paid in the women's colleges to this important item of mental hygiene

OVERSTRAIN

Overstrain at work is another factor very frequently blamed for breakdown but practical experience shows that it often masks much more significant events at home One elderly lady who arrived with this diagnosis in such a condition that it seemed unlikely she would ever work again finally admitted that a rascally relation had appropriated all her savings, and she had been afraid to tell anyone for fear he would be prosecuted She was referred to her solicitor, and a few months later was at work bright and smiling, the relative having been made to disgorge The lack of proportion shown is sometimes rather startling A noisy classroom was solemnly and exclusively blamed in an anxiety neurosis where a young married woman had deliberately decided that children would be an unnecessary interruption to a career.

PARENTAL FIXATIONS

Without entering into contentious theories of the origin of nervous conditions, it may be accepted that a person's attitude to authority and his own exercise of authority is very much determined by his attitude to his parents This is particularly true of the Peter Pan type of person who has never properly grown up, and maintains an infantile attitude to his relations Even on brief contact it is impossible not to be struck by the extreme childishness of some neurotics Some of them, even women of 40, will bring a parent into the room to speak for them, although they maintain they are cured and anxious to return to work A woman of nearly 30 is found to be sleeping of choice in the same bed as her mother; another woman of 55 says she cannot take the holiday her doctor suggests as she is "such a home bird," and has never left big sister! Nearly all this group (and it is a large one) have very similar school troubles which are commonly regarded as the cause rather than the effect of their mental condition To every difficulty (especially if it involves a clash of will with an older person) they can only oppose the weak ineffectual protests of a child, and a flight into disease is a natural escape from situations in which they find themselves powerless It is obviously very desirable to deal with these "parental fixations" as early in life as possible They ruin a woman's career (they are significantly rare in head teachers) and interfere seriously with her chance of marriage. The most tragic results, far too common among professional women, are seen in later life In old age parents need the support of a mature independent woman, not a clinging child, and they invariably despise and turn against the daughter who has never grown up, even if the situation should be of their own making

Teachers are more fortunate than most professional women in that they can have the necessary time and money to recover from a deep-seated neurotic illness They are doubly fortunate, however, if their medical attendant uses his tact and skill to discover an unsolved conflict or hidden terror behind the ostensible cause before ordering prolonged rest A teacher told me that she had gone to her family doctor very ill and miserable, and complaining of overwork, which she genuinely believed accounted for her symptoms As she did not improve in a week or *two off* duty he insisted on investigating further, and at last she confessed to a cancer phobia, born of family legends, and nourished by the anti-cancer propaganda of a well-known layman As she said, in a few minutes' talk her doctor relieved her of a load of torment, and saved her from *months* of illness I hope it is permissible to note here that the affectionate loyalty and appreciation of their doctor's services shown by these teachers goes far to disprove the gloomy rumours current as to the decline of the Family Doctor

CONCLUSION

The foregoing observations although based mainly on a study of teachers, would probably apply mutatis mutandis to women in other professions A comparison with domestically occupied women would be fallacious as involving the question of the effects of marriage As the number of married women teachers in the London service is steadily decreasing and as many of those still working are handicapped by special disadvantages, such as an invalid husband, I have omitted from this survey consideration of the effects of marriage on women's work But there seems to be *no* reason to think that employment in the brain-working occupations outside the home has any detrimental effect on women's

The Menopause

The last group of the special ailments of women is that associated with the menopause, a period to which enormous significance is attached. Indeed, every untoward experience between 40 and 55 tends to be related to this physiological change. There is no denying the importance of what is happening. As a necessary part of the general atrophy of the reproductive organs, which is the essence of the change, the ovarian secretion gradually ceases and the whole elaborate and closely interdependent system of endocrine glands has to readapt itself to an altered condition of affairs. It is obvious that where there is already a lack of harmony in the endocrine system, or where for some reason the general shrinkage is irregular in its course, physical and mental signs of lack of endocrine balance will appear. To the endocrine enthusiast, who sees the woman even more than the man as the plaything of her ductless glands, these simple physiological facts are enough to account for any conceivable phenomenon, and popular superstition once again finds itself supported by modern science. There seems to be no good reason, however, why the degenerative changes in the reproductive system should not be accomplished as smoothly and with as little constitutional disturbance as the coming of puberty in a healthy girl. It is reasonable to demand that the classification of a mental or physical abnormality as due to the menopause should be a question of evidence in each case and not a generalisation based on the patient's age.

The practice of loosely attributing every ailment to the menopause has two very common and disastrous results. (1) the real causal condition (mental or physical) is apt to be overlooked and left untreated, or if treatment is recommended the patient ignores the advice. Neglect of uterine hæmorrhage, due to cancer, is a common example, but much more frequent is the failure to apply rational treatment to the neuroses and psychoneuroses of middle life because of this obsession. Many such examples might be quoted from the series under survey. (2) A special menopause-phobia may be set up which aggravates any pre-existing mental or physical weakness, and may itself make the patient seriously ill. This often occurs when there is no physical evidence of the menopause at all. One woman has been putting forward "the change" as a cause of her numerous nervous breakdowns for eight years. Her periods are still perfectly regular, and she has no sign whatever of endocrine disturbance. In the worst cases this dread is the last thing the patient will acknowledge.

Many of the women now passing through the climacteric were reared in a bad tradition of physiological ignorance, and they have no means of repelling the alarming superstitions about sex functions which circulate orally. I have found a notion, for example, among elderly neurotics that if they pass through "the change" with no discomfort they must "pay for it" by a nervous breakdown later.

The true facts of the matter are very difficult to ascertain, but inquiry from the older patients in this series and from other professional women shows that the vast majority of women pass through the climacteric with no more than a passing discomfort, and little if any disturbance of work. Flushes, sweats, headaches, dizziness, and difficulty in mental concentration make up the usual syndrome, but many women seem to escape altogether. Only 12 cases in all my series had symptoms definitely to the menopause, and they made good recoveries in one to three months, except where there was a definite pre-existing neurosis. No case of insanity, even remotely associated with the menopause, has been traced in the 18 months covered by this survey, but pre-existing anxiety neurosis or neurasthenia are for obvious reasons liable to become worse at the climacteric. No woman can be expected to *like* such a concrete reminder that middle age is upon her, and those of unstable or imperfectly adjusted temperaments will inevitably find adaptation to this new phase of life a difficult matter. Of the "geyser-like eruption" of the emotions which is said to precede the physical signs, I have, however, been unable to discover any traces. As far as my observation goes, the neuroses due to emotional repression seem to be much more common in the middle thirties than the forties. One finds that cantankerousness and groundless suspicion are not the monopoly of any one age-period; it is true these characteristics tend to harden into definite delusions in the later forties, but that is true of men as well as women.

The following table will give some idea of the relation of age in women to neurotic conditions and to the menopause. The cases analysed are unselected, they comprise all teachers seen by me as absenting themselves from work on certificates of "nervous debility," &c., over a period of 18 months.

—	20–	30–	40–44	45–49	50–54	55–59
*Neuroses and psychoneuroses	42	56	30	35	30	31
Menopause	—	—	1	3	6	1

* No comparable figures exist for men.

It is interesting to note that the *total* absence due to "menopause and diseases of women" over a period of 15 years only amounted to an average of 0.13 day per year for each single woman and 0.24 day for each married woman, excluding pregnancy (Mr. J. Y. Hart).

Average days' illness per annum, 1904-19

Nature of illness	Men	Single women	Married women
Pulmonary, throat colds and influenza	2.08	3.50	3.91
Nervous and mental	0.58	1.43	1.98
Gastric	0.34	0.63	0.85
Rheumatism and synovitis	0.31	0.38	0.65
Infectious disease	0.18	0.33	0.28
Debility and anæmia	0.11	0.33	0.36
Heart	0.11	0.21	0.14
Ophthalmic	0.06	0.13	0.13
Dental	0.03	0.08	0.08
Menopause and diseases of women	—	0.13	0.24

There would in consequence seem to be no reason for the custom adopted by certain Government departments and large commercial houses of allowing their women employees one day's holiday a month. The practice adopted by a famous institution of getting rid of its women employees at 45 is equally unnecessary. These so-called concessions are very detrimental to the status of professional women.

Investigation of Nervous Symptoms

Of the *functional neuroses* my series contained 240 cases. These conditions are particularly common in teachers of both sexes, probably because of the constant strain on the attention and the enforced contact with many different personalities involved in teaching. Mr. Hart found that "nervous and mental conditions" were responsible for 12.8 per cent of the total absence on sick leave among men, 17.4 per cent in single women, and 17.2 per cent in married women. They entailed absences amounting to 0.58 day per annum for each man, 1.43 day for each single woman, and 1.98 day for each married woman over the 15-year period.

The 240 cases under survey included every form of neurotic and "mental" disturbance from slight fatigue and depression to certifiable insanity. No attempt at classification was made as acquaintance with most of the patients was necessarily too brief, though some were seen three or four times. Hysteria seems to be very rare, neurasthenia is most common, and anxiety neurosis a good second. I have been struck by the importance of nervous disease as a cause of unhappiness. The woman with inoperable cancer is process of absorption of a peritoneal or other animal ligature is to be found The interpretation of the appearances seen in our microscopical preparations of films from Ziegler chambers was greatly assisted by a study of papers [6] by Miss Greenwood Miss Greenwood's observations were conducted on living specimens of amœba proteus and actinosphœrium, and she was able to follow in these animals under the microscope all the visible phenomena of the ingestion of prey

> "The food most suitable to these forms is unshielded non-coagulated proteid matter A low degree of vitality, a diminished activity of the protoplasm renders an organism easier prey, more readily captured, and more readily absorbed Little monads, euglenæ, and algæ, co existing in the same water with amœba proteus, were by it ingested A fluid medium in the food vacuole of the amœba appears essential for the manifestation of primitive digestive activity The absence of a vacuole around ingested material may indicate that it is innutritious, and thus nutritive material may be distinguished from innutritive"

In the experiments of Sir Charles Sherrington and myself, successive immigrations of cells were observed to enter the Ziegler chambers The only cell which had a permanence of sojourn in the experimental chambers was the wandering connective tissue or plasma cell The place of amœba proteus and actinosphœrium was taken by the connective tissue cell, which may be described as a hot-house variety of amœba The connective tissue cell was observed ingesting in its food vacuole living prey—viz, a leucocyte or a red corpuscle It found its unshielded non-coagulated proteid food to perfection in the dead or dying leucocyte In some vacuoles the captured leucocyte or red corpuscle was more or less altered, but still perfectly easily recognised, while in others only a granular débris remained that furnished no sufficient clue as to its nature, but which seemed to be the remains of digested prey Clearly a proteolytic ferment is secreted in the food vacuole of the connective tissue cell, as it is in the food vacuole of amœba proteus Is it not probable that the wandering and fixed connective tissue cell can exert digestive action also upon material which it does not incept? Monads in Miss Greenwood's experiments which came to rest against the protoplasm of amœba proteus without being taken into the food vacuole became inert and dead, and were apparently acted on by the same agent as was present in the food vacuole She relates, too, the escape of a flagellate infusorian after contact for one hour with an actinosphœrium, and adds that its movements, after escape, were less rapid than usual Suppose a proteolytic ferment is secreted by the connective tissue cell from the surface of its protoplasm, and a leucocyte simply approximated to or partially embayed in the protoplasm, a gradual dissolution of the proteid of the leucocyte in the tissue plasma would occur, and this was observed

The number of instances in which there could be detected in the Ziegler chambers a wholly or partially included leucocyte would not account for the multitude of these cells that disappeared If, on the other hand, a proteolytic ferment is secreted from the surface of the connective tissue cell it makes clear what would otherwise be obscure, the absorption and substitution of organic ligature material, which is certainly not all dissolved in the food vacuoles of the invading cells It would also offer an explanation of the changes that occur in the microscopical appearance of a blood-clot, or of an organic material such as a ligature of catgut, tendon or peritoneum, within a week or ten days of being buried in living tissue At this period the foreign body is already surrounded by a countless number of phagocytic cells, some of which have commenced to invade it The outline of the cells of a blood-clot becomes obscure and the surface of a section of tendon, of catgut or peritoneal tissue tends to become more opaque and to lose all indication of structure long before the connective tissue cell is in actual contact with the parts so altered Obviously some chemical agent is at work, which is the more potent, and the more effective, in the initiation of the dissolution of the foreign body, the closer the foreign body is to the connective tissue cell There are many analogies supporting this view of the action of the connective tissue cell 1 All the known ferment-manufacturing cells pour their secretions into the world outside themselves 2 In the typical process of ossification the osteoblasts of Kolliker cause absorption of the walls of the primary areolæ by means of a secretion from their surface 3 The myeloplaxes of bone cause absorption of bone 4 The same thing occurs in rarefying osteitis In the three latter examples the cells are of mesoblastic or connective tissue origin

As the connective tissue cells increase in number in the Ziegler chambers they form cell-islets or colonies, which surround the stores of nutriment that is gradually dissolved and digested At first the shape of those cells, which are immediately next to the kernel of nutritious matter in the islet, is irregular, and suggests amœboid movement of the protoplasm of the cells, later, each cell becomes regularly fusiform, and is applied by its side to the material, which gradually disappears The captured food comes to be encircled by chains of fusiform cells set concentrically around it This is what happens when any foreign body, such as a ligature or a blood-clot, lies within a wound that heals over it The fusiform fibroblasts slowly exert the same solvent action upon the imprisoned material as did their amœboid ancestors No doubt the more easily affected portions of the material are the first to go into solution and disappear, leaving a constantly less amenable residue and a less nutrient one Perhaps it is in accordance with the decreasing supply of food that the cells, in contact with the residuum of food undergo a gradual change and lose their pristine elasticity of form. They assume the spindle shape, and a fibrillated intercellular cement substance comes into existence between them Much as amœba under adverse conditions assumes an encysted form so when food is scanty do the inherited tendencies of the fibroblast lead it into states of quietude or encystment Encapsulation, it is important to note, of a foreign body, such as a blood-clot or a ligature, is a stage in the process of absorption

For many years after catgut was reintroduced to the notice of the profession in 1869 by Prof Lister, then of Glasgow, it proved in the hands of many surgeons for various reasons unreliable in use Bryant, of Guy's, read before the Clinical Society on Oct 12th, 1877, a paper in which he reported the ligation of the external iliac, common carotid, right subclavian, and common femoral arteries with carbolised catgut. From our present-day knowledge the results were unsatisfactory but Bryant expressed his belief that "we have in the carbolised catgut the best ligature at our disposal" Callender, of St Bartholomew's, read a paper before the Clinical Society on Feb 8th, 1878, in which he recommended the use of tendon ligatures instead of catgut ligatures He writes: "Catgut occasionally fails to arrest the blood stream for a time sufficiently long to allow of the cure of the aneurysm, and this failure imperils the life of the patient" The kangaroo-tendon ligatures were sent to Callender by Hulme of Guildford, who had received them from Girdlestone, of Melbourne Callender says "that in tendon ligatures we possess a material which resists the solvent action of its surroundings in a wound longer than catgut. Its strength is sufficient, it ties better knots and the knots do not slip" He adds "As the supply of these tendons is distant I am having prepared ligatures which are made from the tendons of the horse They have much the same characteristics as the tendons from the marsupial"

In some cases the failure of the operation was not due to the catgut or tendon ligature employed Sir Thomas Smith [8] ligatured the common iliac artery with kangaroo tendon The next day pulsation was bodies or minds. They start with slight initial handicaps in the form of (*a*) a higher sickness rate than men in all forms of disease, (*b*) a liability to a special group of ailments of their own, (*c*) a tendency to age sooner and more suddenly than men. My conclusion, based certainly on impressions rather than on exact figures (which do not in fact exist), is that all these handicaps have been exaggerated and can be considerably reduced by improved hygiene. In the days of under-payment and restricted opportunities of work the hygiene of women was far inferior to that of men as regards clothes, exercise and diet. They have much leeway to make up especially as regards exercise and diet, but every year brings a demonstrable improvement. Education in the hygiene of the special ailments of women has hardly begun but is already making a substantial difference in reducing disability. Without undue optimism it seems reasonable to consider that preventive medicine has yet much to contribute to the problem of maintaining the physical efficiency of the professional woman.

SOME EXPERIMENTS ON THE CONDUCT AND FATE OF A LIGATURE MADE FROM THE PARIETAL PERITONEUM OF THE OX

WHEN IMPLANTED IN LIVING TISSUE *

BY SIR CHARLES BALLANCE, K C M G, C B, M V O, M S LOND,
CONSULTING SURGEON, ST THOMAS'S HOSPITAL.

(*With Illustrative Plates*)

IN a volume [1] entitled "Ligation in Continuity," published by Mr W Edmunds and myself in 1891, the figures 129 and 130 represent the microscopical appearance of a peritoneal ligature after being applied respectively 14 and 55 days around the carotid of a horse (Figs 1 and 2).

Some three or four years previous to the publication of this book, when showing microscopical sections of kangaroo-tendon ligatures undergoing absorption to the then Sir Joseph Lister, he remarked "that the best material for an absorbable ligature was white fibrous tissue, and that the purest white fibrous tissue in the body was the peritoneum, he thought, therefore, that the best material for a ligature would be peritoneum, and that he had himself tried it, and with success, on the carotid artery of a calf."

Accordingly, we obtained from the butcher a large piece of the parietal peritoneum of the ox, it was fixed and stretched on a board, cut into strips, and twisted into ligatures, which were further prepared by immersion in solutions of chromic acid and carbolic acid. However, these home-made ligatures were not very satisfactory, and we asked Messrs Macfarlan, of Edinburgh, to prepare some for us, these ligatures were made in various sizes, and were from 18 to 20 inches long. Subsequently Messrs Macfarlan made peritoneal ligatures for us, not directly from the ox peritoneum, but from gold-beaters' skin, which is ox peritoneum beaten out thin. The peritoneal ligatures thus made resisted absorption for a somewhat longer time than kangaroo-tendon ligature of the same size.[2] The peritoneal ligature seems to satisfy all the tests of a perfect ligature when employed for the ligation of a large artery in continuity. Being of white fibrous tissue, it is of the same structure as the outer coat and sheath of an artery; it is strong, inelastic, round, smooth, pliable, can be made of any suitable size, is easily tied in a knot, is slowly absorbed, and is easily rendered aseptic.

When a ligature is absorbed it is replaced by new living tissue, there is no interval between the living material and the ligature. The arrangement of the fibres of the new tissue is influenced by the structure of the ligature, and the stages in which it has yielded to solution. As Lister explained, "the new tissue takes as a model the old and forms at its expense the old tissue is absorbed by the new, and as the old is absorbed new is put down in its place."

Lister noted too that a peritoneal ligature placed round the carotid artery of a calf,[3] and examined 30 days afterwards, appeared on casual inspection still to be in place but it was no longer the ligature that was visible encircling the artery, for by absorption and substitution it had been almost entirely transformed into a band of living tissue. This band had, indeed a deceptive resemblance to the former condition but on careful examination it was seen to be continuous in structure with the arterial wall. In the centre of the loop of living tissue was a remnant of the original ligature (so that in 30 days the process of absorption and substitution was as yet incomplete).

> "The fleshy material around the remains of the loop of the ligature proved under the microscope to be a most beautiful example of fibroplastic structure, the fibres which mainly constituted it being composed of large elongated cells with long processes. It appears, then that by applying a ligature of animal tissue around an artery we virtually surround it with a ring of living tissue, and strengthen the vessel where we obstruct it. The surgeon may now tie an arterial trunk in continuity close to a large branch, secure against secondary hæmorrhage provided always that he has so studied the principles of the antiseptic system, and so carefully considered the details of the mode of dressing, that he can feel certain of avoiding putrefaction in the wound. For my own part I should now without hesitation undertake the ligation of the innominate artery believing that it would prove a very safe procedure."[4]

In "Ligation in Continuity" (Fig 115, p 257) are figured two carotids of the ass ligated with kangaroo tendon. The specimens were obtained 67 days and 77 days respectively after the performance of the operations. The ligatures appear at first sight in place and unaltered, but on transverse microscopical section of the loops of the ligatures they are seen to be entirely replaced by young connective tissue, the dead tendon band being substituted by one of living fibrous tissue.

The question naturally arises as to the nature of the intimate processes of absorption of a peritoneal or other animal ligature. Such a ligature is a foreign body, and all foreign bodies which can be acted on by the living cells and fluids are absorbable, but the time required for absorption and substitution of different materials varies greatly. Silver wire and ivory pegs become pitted on their surfaces after a stay of a few months in the living body. The attack of the living cells on pure gold wire fails, as does also the attack of the body cells on a tracheotomy tube made of platinum. In a case of ligation of the external iliac artery with silk for femoral aneurysm it is interesting to recall what Lister found ten months later—

> "fragments of the ligature of various lengths, many of them greatly reduced in thickness. They had the appearance of being superficially *nibbled* so to speak, *confirming* the impression conveyed by the naked eye characters of the knot, that the silk had been eroded by the absorbing action of the surrounding parts. Indeed, considering the organic origin of silk, the remarkable thing seems to be, not that it should be absorbed by the living tissues, but that it should resist their influence so long."

In a paper published [5] by Sir Charles Sherrington and myself the key to the understanding of the is taking place, either within or without the capsule of fibrous tissue Where a portion of ligature has nearly or completely disappeared, there occurs a yellowish staining of the cells which afterwards disappears

---

* The Medical Research Council defrayed the expenses of this research, and the experiments were performed at the National Research Institute, Hampstead. The microscopical sections were cut and stained by Mr S P Steward at the Royal College of Surgeons of England, by the kind permission of Sir Arthur Keith.

[5] Journal of Physiology, 1889.

Two methods of absorption are shown in Figs 24, 25, and 26 Fig 26 shows a fragment of ligature undergoing absorption within a giant cell, and Figs 24 and 25 show numerous cells encircling a fragment of ligature with certain clear spaces between some of the cells and the fragment of ligature These spaces probably contain the proteolytic ferment in a fluid medium, and if this is so, Miss Greenwood's dictum that "a fluid medium is necessary for the manifestation of primitive digestive activity" is fulfilled In the case of the giant cell (Fig 26) there is no visible space between the protoplasm of the cell and the fragment of ligature, but both in the case of the giant cell and in the other instances where the fragment of ligature is surrounded by many cells, the structure of the fragment of ligature has undergone a change, some parts of it seem not much altered, while in other parts clear spaces appear to exist These spaces indicate parts of the fragment which is already dissolved, and they may contain fluid and the proteolytic ferment

It is not at first easy to find in the sections a fragment of ligature undergoing absorption in a food vacuole of an individual cell In order to do this the granulation tissue in which absorption is actively taking place should be teased out in the fresh state and the cells fixed with osmic acid A few examples of this method of absorption have been seen and three such cells are shown in Fig 27 In some vacuoles a fragment of ligature could be identified, while in others only a granular débris remained that furnished no sufficient clue as to its nature, though the surmise that it is the remains of digested ligature is probably true Many cells have been observed in which the protoplasm was full of granules of varying size, difficult to see, which were not the granules of regular size normally present in the protoplasm In such cells no food vacuole was present, and the impression on the mind of the observer was that this was the last stage of the process of absorption, the food vacuole having given up the granular remains of the ligature to the surrounding protoplasm

In some situations close to a fragment of ligature undergoing absorption (see Fig 16—four weeks—Figs 18, 19, and 20—nine weeks—and Fig 23—13 weeks) the surface of the remains of the ligature when viewed under a high power is seen to be broken up into small islands surrounded by cells Outside these islands are a closely packed mass of cells with oval nuclei In the protoplasm of the cells are several refractile granules of varying size, distinct in some cells and indistinct in others These granules do not belong to the structure of the cell itself, and appear to be minute particles of some foreign body in process of dissolution

When all the ligature has been absorbed and replaced by the living cells, the latter lose their pristine flexibility of form, become spindle-shaped, and spin fibrous tissue The outline of the original dead material of ligature can be recognised by the shape and size of the fleshy mass of new living tissue which has been substituted for it

ABSORPTION EXPERIMENTS

These were carried out by passing the ligature through a portion of the muscle of the rabbit, the animal being anæsthetised with ether The ligature was tied with a reef-knot All the wounds healed by first intention Some experiments were done with catgut in order to contrast the time of absorption of this material with that of the ox peritoneum ligature

DESCRIPTIONS OF ILLUSTRATIONS

(SEE ILLUSTRATIVE PLATES AND FIGURES IN THE TEXT)

DRAWINGS ILLUSTRATING CERTAIN OLD EXPERIMENTS (Figs 1–3)

FIG 1 —*Ox peritoneum ligature* which had been applied for 14 days round the carotid artery of the horse (× 50) The ligature was made by Messrs Macfarlan, of Edinburgh, about the year 1887 The folds formed by the twisting of the membrane are seen separated by white spaces The side away from the artery is uppermost, and in this situation many cells have collected, absorption has commenced The fibrous structure of the ligature can no longer be seen (See "Ligation in Continuity," Fig 129)

FIG 2 —*Ox peritoneum ligature* which has been applied for *55 days round the carotid artery* of the horse (× 50) The ligature was made by Messrs Macfarlan, of Edinburgh, about the year 1887 The spaces between the folds into which the membrane was thrown in manufacture are seen as white streaks, and it is along them that on the side away from the artery that cell invasion is occurring. It is only on this side that absorption and substitution is actively proceeding The fibrous nature of this ligature can no longer be seen. (See "Ligation in Continuity," Fig 130)

FIG 3 —*Chromic catgut ligature which had been applied for three days round the carotid artery* of a sheep (× 90) The operation was performed at the Pathological Institute at Leipzig in the summer of 1884 The microscopic sections were cut and mounted in the autumn of that year at St Thomas's Hospital The actual section from which the above drawing was made is beautifully preserved (1925) In the lower part of the drawing the arterial wall under the knot of the ligature is shown, but it does not appear in the section from which this drawing was made It is copied from a drawing of another section in order to complete the picture of the ligation of the artery

The villi of the mucous coat of the sheep's intestine, from which the ligature was made, are clearly seen, as are also the fissures formed by the twisting of the gut A dense mass of cells are collected on the side of the ligature away from the artery The tension between the arterial wall and the side of the ligature next to it interferes with the cellular invasion in this region

DRAWINGS ILLUSTRATING THE STRUCTURE OF CERTAIN LIGATURES (Figs 4–11)

FIG 4 —*Ox peritoneum ligature* (× 100) made from wide strips of tissue The ligature consists of pure white fibrous tissue The section looks like a section of a fibroma. The folds formed by twisting the membranes in manufacture are few in number and are separated by white streaks

FIG 5 —*Ox peritoneum ligature* (× 100) made from narrow strips of tissue The ligature is composed of pure white fibrous tissue The folds formed in manufacture by twisting the membranous strings are numerous, and are seen separated by white streaks

FIG 6 —*Portion of ox peritoneum ligature, seen in Fig 4, more highly magnified* (× 160) The section shows in detail the fibrous structure of the ligature

FIG 7 —*Gold-beaters' skin ligature* (× 100) This ligature (No 2 size) was made by Messrs Macfarlan of Edinburgh, about the year 1888 It was sent to me in a bottle containing carbolic oil, and has remained in this medium ever since (1925) Gold-beaters' skin is made from ox peritoneum and the structure of gold-beaters' skin ligature is, therefore, white fibrous tissue, compare with Fig 4

FIG 8 —*Portion of gold-beaters' skin ligature* Seen in Fig 7, more highly magnified (× 160) Compare with Fig 6 The section shows in detail the fibrous structures of the ligature

noticed to have occurred He attributed the looseness of the loop of the ligature to the first part of the reef-knot slipping before the second part was completed Thus, although the knot was secure, the loop was loose, this, too, was no doubt what occurred in other cases

In Bryant and Callender's time the manufacture of the catgut ligature was unsatisfactory, and the nature of the process of absorption of an animal ligature was not clearly comprehended Even as late as 1890 I found, on examining microscopical sections of catgut obtained from various sources, that they showed the presence of the villi of the small intestine (Fig 3), though Lister had directed that the mucous membrane of the sheep's intestine should be removed by mechanical means before the material was cut into strips, and twisted into a thread of surgical catgut Recently, in examining microscopical sections of catgut kindly supplied to me by Mr Merson, of Edinburgh, I found that the appearance of the sections did not correspond with the appearance of the sections of ox peritoneum ligatures also supplied by Mr Merson The difference is probably due to the presence in the catgut ligature not only of fibrous tissue but also of muscular tissue During the Great War whenever I had the opportunity of ligating one of the large arteries I employed kangaroo-tendon ligatures (Van Horn) (tendon is a form of white fibrous tissue) tied with a stay-knot, and in every case success was attained

I am informed that it is increasingly difficult to obtain kangaroo tendons, they are now used for other purposes than surgical ligatures Hence, I think Lister's peritoneal ligature might well replace the use in surgery of kangaroo tendon A study of the figures illustrating this paper shows that the peritoneal ligature is particularly well adapted for this purpose, especially if chromicised, which process delays the absorption of the ligature and is in no way surgically disadvantageous

Mr Merson kindly had some ox peritoneum ligatures prepared for me They were of various sizes from No 00 to No 8 and were either plain or chromicised as follow 1 *Plain ligatures prepared from the tissue in its natural state unhardened in any way* whatsoever 2 *A* ligatures—chromicised—prepared from broad strips of peritoneum tissue ¾ to 1 inch in width 3 *B* ligatures—chromicised—prepared by twisting a number of very narrow strips of tissue ⅛ to ¼ inch in width

Mr Merson writes that "he is quite prepared to find that *B* strings made from very narrow ribbons of tissue will break down more readily than those made from broad strips" It was to be expected that with many more channels leading into the interior of the ligature, formed by the twisting of several narrow strips of tissue, that the invading cells would have greater facilities for reaching the interior of the ligature In this way the ligature is split up into little islands which are encircled by cells, so that absorption and substitution is much facilitated

On the other hand, when the peritoneal ligature is made from broad strips of tissue the result is that absorption takes place mainly from the surface as it does in the case of kangaroo tendon A chromicised ox peritoneum ligature of suitable size, made from broad strips of membrane, appears to be a perfect ligature for the ligation of a large artery in continuity, or for use in the operation for the radical cure of hernia There are many other operations in which the ox peritoneum ligature either plain or chromicised, might be usefully employed, seeing that this ligature resists absorption for a somewhat longer period than catgut It appears to me that ox peritoneum ligature of all sizes and for all purposes is superior to catgut, it is composed of one tissue and one tissue only—white fibrous tissue; but unless made in large quantities it would be probably more expensive than catgut

To conclude, this research gives support to the opinion expressed by Lister long ago that the best ligature material is peritoneum, and is published as a humble tribute to the immortal memory and genius of the Master

THE ABSORPTION OF THE OX PERITONEUM LIGATURE AS SHOWN IN THE DRAWINGS AND FROM THE STUDY OF THE MICROSCOPICAL SECTIONS

When an artery is ligated the attack of the invading cells on the ligature is at first, and, indeed, for a long period, confined to that surface of the ligature which is farthest from the arterial wall This is due to the tension of the structures within the loop of the ligature (see Figs 2 and 3) The same fact has been observed in the experiments in which within the loop of the ligature was compressed not an artery but muscular tissue (see Fig 18)

The anatomical features of plain and chromicised ligatures when observed under the microscope are identical Chromicised ligatures and those made from broad strips of membrane resist absorption for a much longer period than plain ligatures and those made from narrow strings

The multitude of cells which collect around the ligature is a striking and early manifestation of the reaction of the tissues to the presence of a foreign body in their midst The cells enter the cracks and fissures of the ligature, when these exist, and divide it successively into small islands As absorption of the fragments of ligature proceeds the columns of cells within the cracks and fissures widen, and as the dead tissue disappears living tissue is put down in its place At last the fragment of the ligature is completely dissolved and its place is occupied by cells which, having completed their duty and destiny, become elongated, and spin fibrils of connective tissue

The cells, while actively engaged in the warfare against the ligature, are of all shapes, their protoplasm giving the appearance of amœboid movement The nuclei of the cells are generally oval in outline, indicating their descent from connective tissue corpuscles A group of cells surrounding the main mass of the ligature assume a spindle shape This capsule of young fibrous tissue is not wide but it shuts off the dead tissue from the rest of the body Within it absorption of the surface of the ligature proceeds Some three or more weeks later it can be observed that some unabsorbed fragments of the ligature are outside the capsule of fibrous tissue so that absorption of the surface of the ligature has taken place in an irregular manner The capsule becomes smaller as the enclosed mass shrinks in size The surface of the ligature has resisted absorption in some places for a longer time than in others It would seem that as the ligature is absorbed certain cells within the encircling band of fibrous tissue enter the resting stage and form fibroblasts, while the outer layers of spindle cells of the band of fibrous tissue resume an active life, being stimulated thus to act in consequence of the presence of unabsorbed fragments of ligature outside the encircling band of young fibrous tissue Thus, as the mass of ligature shrinks in size, the fibrous capsule still remains in contact with it, the capsule of the ensheathing fibroblasts diminishing in diameter as the foreign body is absorbed On the other hand, in those instances in which absorption of the ligature mainly takes place by the action of the cells which penetrate into its interior, the original circle of fibrous tissue remains in place and forms the outer limit of young fibrous tissue which is substituted for the ligature

The tissue outside the capsule of fibrous tissue when there are unabsorbed fragments of ligature in this situation is composed of a numerous army of active single cells, giant cells, and a great number of newly formed capillaries The vascularity of this tissue is a necessary part of the process of absorption for the dissolved material of the ligature must ultimately be carried off by the blood stream and by the lymphatics, and, further, it is from the blood that the cells obtain materials for their sustenance and for the manufacture of a proteolytic ferment Giant cells are numerous wherever active solution of the ligature

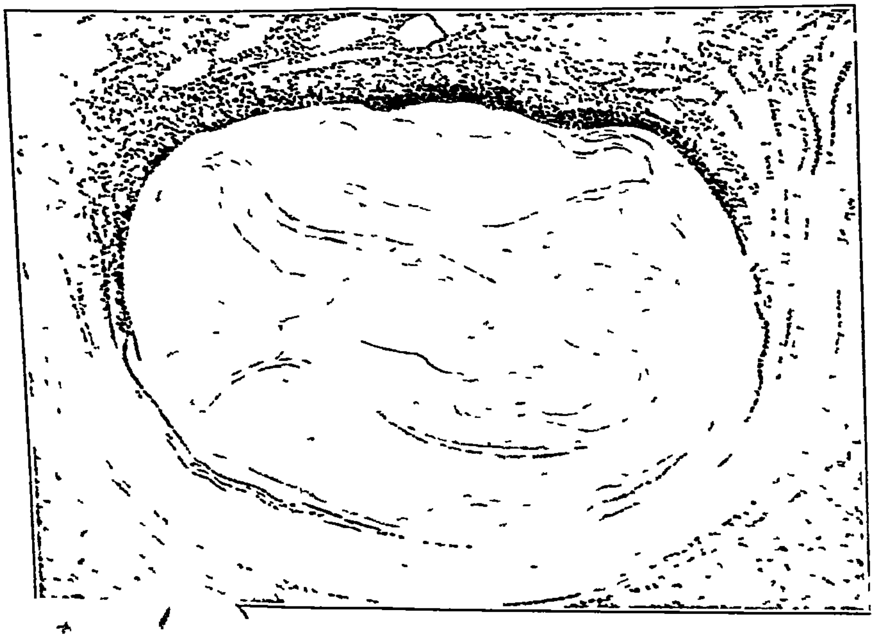

FIG. 7

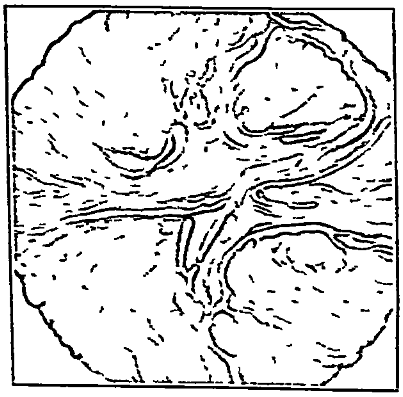

FIG 9 —*Kangaroo-tendon ligature*, medium size, Van Horn (× 160) A tendon consists of bundles of white fibrous tissue with chains of cells The cells partially ensheath the bundles of fibres and are connected by a network of branched processes The structure of tendon is well seen in the section

FIG 10 —*Portion of catgut ligature* Merson (× 160) Made from narrow strips of tissue The ligature does not appear to be made up, as is ox peritoneum ligature, of fibrous tissue only Under a one-twelfth oil-immersion lens no markings indicative of muscular tissue are visible, but there can be seen faint longitudinal striations which may be due to the presence of fibres of the longitudinal muscle coat as well as of the fibres of the peritoneal coat of the gut. The curious angular markings on the section may possibly have been caused by the scraping process employed to get rid of the mucous membrane of the gut during the process of manufacture as originally directed by Lister

FIG 11 —*Portion of chromic catgut ligature*, size No 3, Van Horn (× 160) The structure of the ligature appears homogeneous It is not possible to identify under the microscope either the fibrous or muscular coat of the sheep's intestine There are no longitudinal striations

DRAWINGS ILLUSTRATING THE ABSORPTION OF THE OX PERITONEUM LIGATURE (FIGS 12–23)

FIG 12 —*Catgut ligature* (plain, not chromicised), showing absorption after one week (× 38) Made from narrow strips of tissue Note the cellular invasion and the absorption of the ligature already occurring, especially along its lower border

FIG 13 —*Ox peritoneum ligature* (plain, not chromicised), showing absorption after one week (× 38) Made from narrow strips of membrane Note the outline of the ligature is more distinct than the outline of the catgut in Fig 12, in which absorption is more advanced The invading cells are advancing into some of the cracks and fissures The fibrous structure of the ligature cannot be made out

FIG 14 —*Ox peritoneum ligature* (plain, not chromicised) (× 38), showing absorption after three weeks Made from narrow strips of tissue Note the cellular penetration and absorption of the ligature along the edges of the numerous folds caused by the twisting of the strips of membrane in manufacture The active cells invading the ligature take a deeper stain than those surrounding and encapsulating it As absorption proceeds the channels in the ligature become wider, the dead ligature material being replaced by living cells

FIG 15 —*Catgut ligature* (plain, not chromicised) (× 50), showing absorption after four weeks Made from narrow strips of tissue Note the great cellular proliferation and the almost complete absorption of the ligature

FIG 16 —*Ox peritoneum ligature* (chromicised) (× 60), showing absorption after four weeks Made from wide strips of tissue Note the cellular invasion from the surface of the ligature The outline of the drawing indicates nearly the size of the original ligature, its outer surface having been absorbed and substituted by living tissue The fibrous structure of the ligature cannot be made out The breaking up of the outer surface of the ligature into little islands surrounded by cells is well seen Contrast with Figs 14 and 17

FIG 17 —*Ox peritoneum ligature* (chromicised) (× 38), showing absorption after seven weeks Made from narrow strips of membrane Note the slower absorption of the ligature as compared with the ligature illustrated in Fig 14 The interior of the ligature is being divided up into small islands Each island is in part or wholly surrounded by the invading cells This makes more easy the process of absorption Compare with Fig 16 and note the scheme of absorption is different in the two experiments

FIG 18 —*A sagittal section through the ligatured muscle and through the knot and loop of the ligature of* chromicised ox peritoneum ligature (× 20)—nine weeks The ligature was made from broad bands of membrane The muscle included in the ligature is strangled and dead Cells are invading the dead muscle from each side, but the tension between the muscle and the side of the loop of the ligature next to it has interefered with the cellular invasion in this region There is still much dead muscle to be absorbed The external half of the loop of the ligature in the lower part of the drawing has been absorbed, and the upper half of the corresponding portion of the ligature under the knot shows about the same amount of absorption The remnant of the knot is visible as numerous fragments of ligature surrounded by an innumerable army of attacking cells *E* is the site of high power drawing of Cells 2 and 3 in Fig 27

FIG 19 —*A horizontal section through the middle of the loop of the ox peritoneum ligature* seen in the lower part of drawing Fig 18 (× 38)—nine weeks In the main the ligature is being absorbed from the surface The original size of the ligature nearly corresponds to the oval area shown in the drawing In the mass of cells immediately surrounding the ligature are numerous capillaries, fragments of ligature as yet unabsorbed, and many giant cells containing in their protoplasm or surrounding with the help of other cells portions of ligature in the process of absorption, but these details require a higher power (Zeiss D lens) to be observed The yellow bands of material in the right lower portion of the drawing may be muscular fibres being absorbed *B* is the site of the high power drawings Figs 24 and 25

FIG 20 —*A horizontal section above the middle of the remains of the knot of ox peritoneum ligature* seen in the upper part of the drawing Fig 18 (× 38)—nine weeks The drawing shows two fairly large portions of ligature in the process of absorption from the surface In the mass of cells are seen a great number (with a higher power) of fragments of ligature in the stage of active absorption and substitution by the cells Only the larger fragments are visible in the drawing Giant cells are to be seen also with a high power dotted about among the army of single cells In this case the knot was probably not tied tight, hence the invading cells were able to reach its interior and attack the strands, of which the knot is made up, separately *C* is the site of the high power drawing Fig 21 *D* is the site of the high power drawing of Cell 1 in Fig 27

FIG 21 —*High power drawing of fragments of ox peritoneum ligature* seen at *C* in Fig 20 within the fibrous capsule (× 200)—nine weeks Fragments of the ox peritoneum ligature are seen surrounded by a multitude of single cells and a few giant cells Absorption is taking place

FIG 22 —*Section through the knot of a chromicised ox peritoneum ligature* (× 30)—13 weeks The ligature was made from broad bands of membrane The drawing shows that absorption has taken place from the surface, the cells having been unable to penetrate between the various strands of the knot, as is seen in drawing Fig 18 Below, the immense cellular invasion extends as far as the muscle, but above, the granulation tissue was broken off in making the section The amount of absorption already effected is considerable The tissue of the knot extended half-way at least to the muscular tissue in the lower part of the drawing, and it is probable that the same amount of substitution of living tissue for the material of the ligature has occurred in the whole circumference of the knot In the vascular tissue stained blue outside the surviving portion of the knot are to be seen in this drawing many lighter areas which represent fragments of ligature that have as yet escaped solution Under a higher power these fragments of unabsorbed ligature are very numerous, and giant cells and capillaries are visible around them The remnant of the knot is surrounded closely in most places by a narrow band of young fibrous tissue No evidence of fibrous structure can be detected in the unabsorbed portion of the ligature

FIG 23 —*A section through the granulation tissue surrounding the unabsorbed portion of the knot of ox peritoneum ligature* seen in Fig 22 (× 38)—13 weeks In one place a considerable portion of ox peritoneum ligature is seen undergoing absorption It may be that this is one of the free ends of the knot of the ligature The rest of the drawing of this section shows very numerous fragments of ligature not yet absorbed Under a higher power giant cells and single cells containing fragments of ligature can be observed and numerous capillaries The whole area of the drawing was obviously originally occupied by the ox peritoneum ligature of the knot *A* is the site of the high power drawing Fig 26

DRAWINGS ILLUSTRATING THE INTIMATE PROCESS OF ABSORPTION OF OX PERITONEUM LIGATURE BY GROUPS OF CELLS, BY A GIANT CELL, AND BY SINGLE CELLS (FIGS 24–27)

FIG 24 —*A fragment of ox peritoneum ligature encapsuled by young fibrous tissue and undergoing absorption* (× 750)—nine weeks Within the capsule in the lower part of the drawing is seen a giant cell, and many clear spaces are visible which may contain a proteolytic ferment in a fluid medium This would explain the slow dissolution of the fragment of ligature which is homogeneous in

appearance and has lost its typical structure The drawing is taken from a spot in Fig 19 marked *B*

FIG 25 —*A fragment of ox peritoneum ligature encapsuled by young fibrous tissue and undergoing absorption* (× 750)—nine weeks Within the capsule in the lower part of this drawing is seen a giant cell, and several wide clear spaces are seen external to the fragment of ligature They may contain a proteolytic ferment (secreted by the cells) in a fluid medium This would explain the absorption of the ligature material The lower part of the fragment of ligature still seems to show some faint signs of structure, but this is probably fallacious, the appearances being caused by the lines of absorption The upper part of the fragment is quite structureless A light area of absorption is visible around a cell which seems to have embayed itself in the substance of the ligature The drawing is taken from a spot in Fig 19 marked *B*

FIG 22

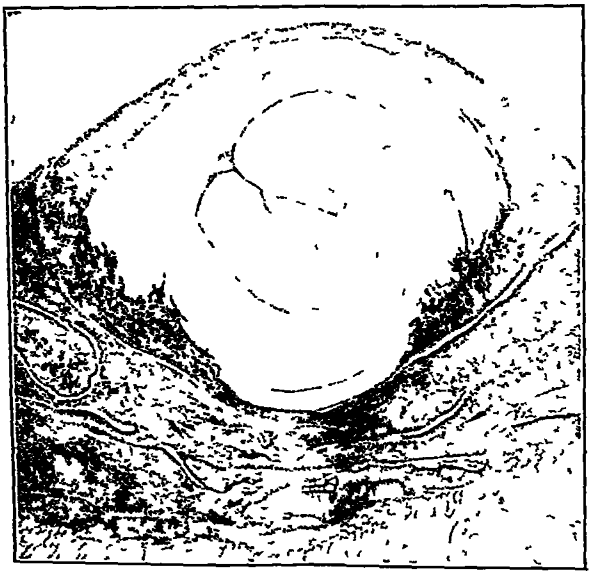

FIG 26 —*A giant cell containing in its protoplasm a fragment of ox peritoneum ligature* (× 750)—13 weeks The protoplasm of the cell is in close contact with the fragment of ligature (*a*) Several light areas crossing the fragment can be seen where absorption has taken place They may contain the ferment in a fluid medium, hence the non-necessity, at this stage, of absorption occurring in a "vacuole" All trace of the fibrous structure of the ligature material has been lost The drawing was made at the place marked *A* in Fig 23

FIG 23

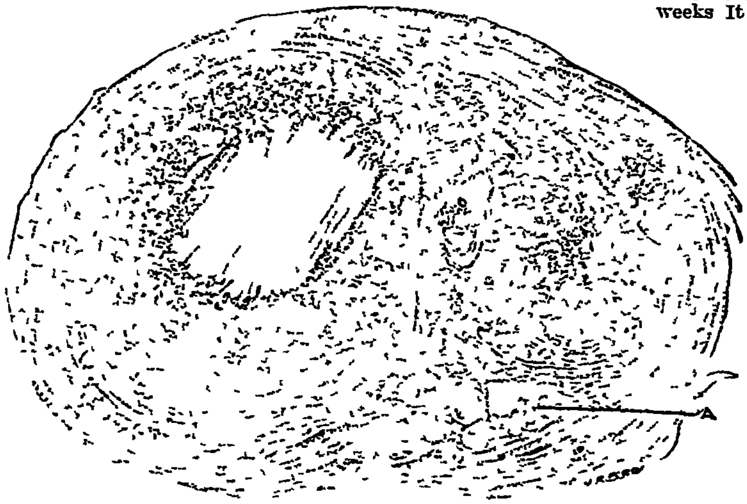

FIG 27 —*Cells digesting ox peritoneum ligature* (× 1100) (I think this is a fair statement, as the ligature is the only material nearby, with the exception, perhaps, of a stray leucocyte or red corpuscle, which the cells could attack and ingest)

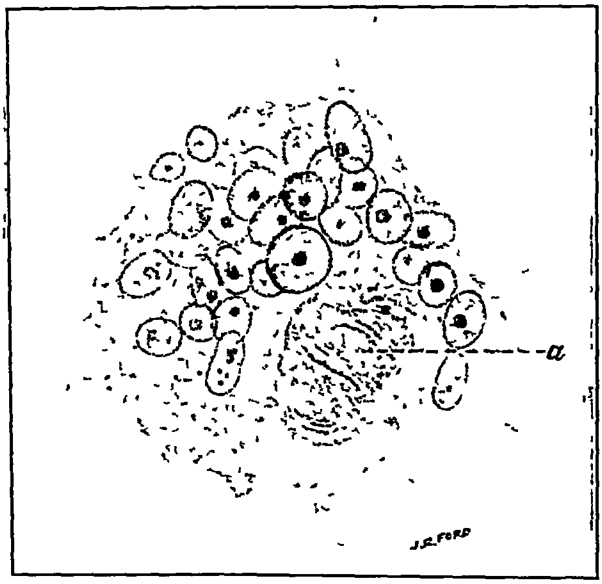
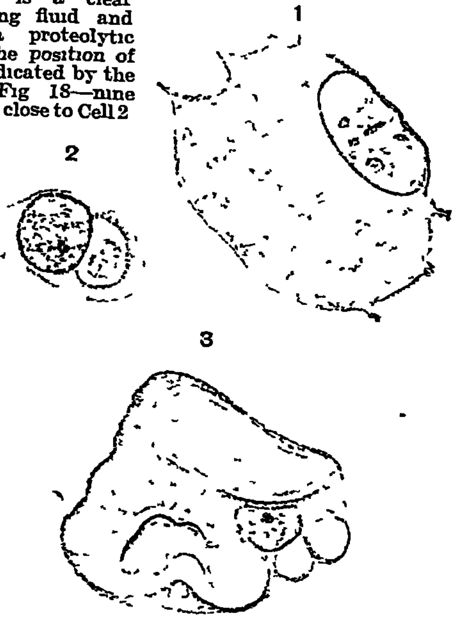
FIG 26



1 *A cell with many small fragments of partly dissolved ligature* in its protoplasm. There is no food vacuole visible, possibly it has completed its labours and shed the debris of the digestive process into the surrounding protoplasm. The position of this cell is indicated by the letter *D* in Fig 20—nine weeks

2 *A cell in the protoplasm of which can be seen a food vacuole containing the remains of a fragment of ligature* Around the fragment is a clear space containing fluid and presumably a proteolytic ferment The position of the cell is indicated by the letter *E* in Fig 18—nine weeks It lies close to Cell 2

FIG 27



3 *A cell in the protoplasm of which are two food vacuoles* In each vacuole is a fragment of ligature as yet not completely digested Around each fragment is a clear space containing fluid and presumably a proteolytic ferment The position of this cell is indicated by the letter *E* in Fig 18—nine weeks

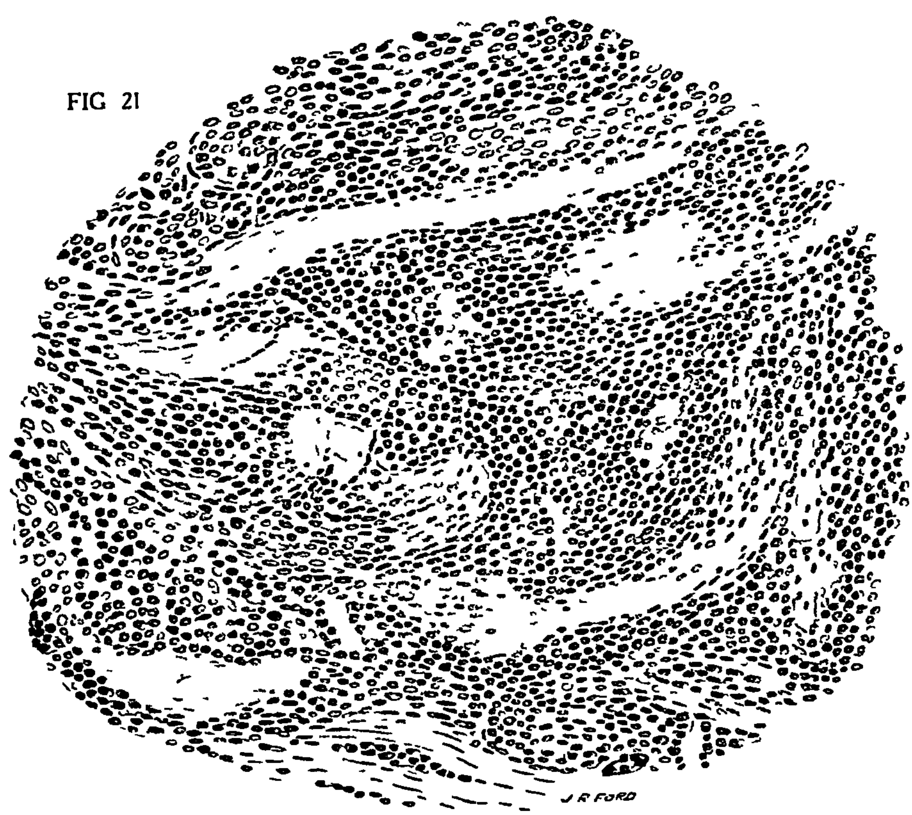

FIG 24

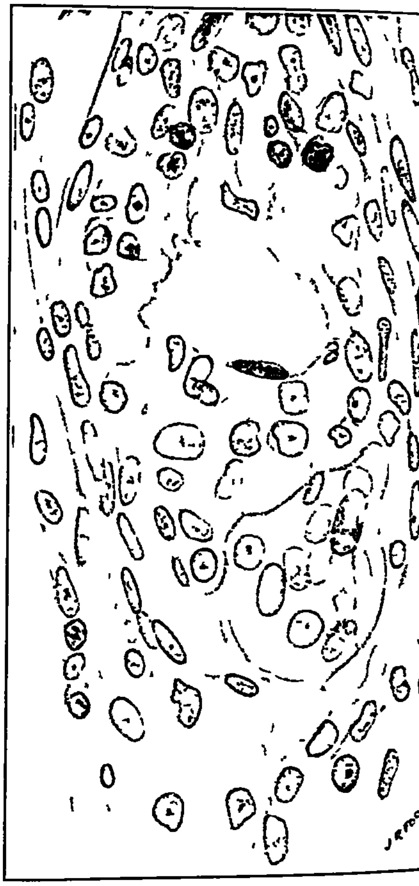

FIG 25

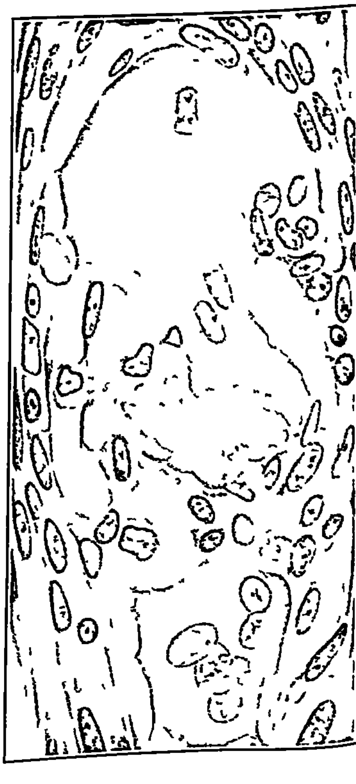

ability, but after exposures of the light-adapted eye to high intensities of white or coloured light, the excitability to that light is diminished and that to the complementary colour is enhanced by the process of induction. None of these effects can fairly be called pathological. Prolonged and intense exposures, however, produce changes which, if not definitely of this nature closely border upon it (Burch), and may be taken to indicate a "physiological fatigue," using the term without prejudice, while, by measuring the critical frequency for the elimination of flicker Grunbaum has brought forward evidence of a true "optical fatigue." These, however, are only extreme experimental cases, and for all practical purposes retinal fatigue does not exist, and the ordinarily visible spectrum may be taken as exerting no pathological effect upon the physiological mechanism of the retina although, as will be seen, these rays can produce definitely pathological effects in another way (by thermic action). Excessive light, especially if the peripheral retina is largely stimulated, may also produce the phenomenon of dazzle, by which the sensation is prolonged after the stimulus is withdrawn. The ease with which "fatigue" can be elicited varies with the colour of the light used (Wanach), being least for the more refrangible rays; similarly, the duration of the dazzle sensation varies with the colour, red passes off first, then green, blue, and lastly violet. Excessive contrasts also of light intensity exert a deleterious effect upon vision, a factor which is largely responsible for the unpleasant sensation of glare.

Those rays below 4000—that is, the longer ultra-violet—produce a most unpleasant visual effect, as is experienced on looking directly at a bare arc or at a mercury-vapour lamp. The former, with its large proportion of highly luminous waves, cannot easily be looked at for long. Fixation of the mercury-vapour lamp for two minutes produces at the time and for a considerable period afterwards an annoying and uncomfortable effect visually and psychically, and a curious general feeling of weirdness and uncanniness. It is difficult to appreciate details, and a central luminous fog floats before the eyes which may persist for some time, or an absolute or relative scotoma develops. This central fog diminishes the visual acuity considerably, it tends to float about, and, curiously, may sometimes be dodged when the visual acuity appears almost normal for a moment. The lack of fixation which it induces, with the consequent effort to maintain it, seems largely responsible for a feeling of fatigue which quickly develops. Erythropsia ("red vision") readily appears after removing the eyes and persists up to two minutes, and is usually followed by a distinct xanthopsia ("yellow vision"). For some considerable time afterwards there is a marked diminution in the power of adaptation, vision in the dark is lowered, night-blindness virtually coming on, and in the sunlight everything takes on a grey tint. *Erythropsia* is a condition wherein everything seems to be tinged with red. It occurs after exposure of the retina to intense light, particularly to light rich in the shorter spectral waves, as, for example, after looking at an arc or after exposure to a flash of lightning or to the light reflected from a snow-field. It occurs more readily when the pupils are dilated, and is especially common after cataract extraction, and sometimes occurs normally on waking first thing in the morning. It may last a very variable time, and the tint of redness varies.

To be distinguished from true "photo-erythropsia" is a similar condition which is said to occur as a neurosis (Wydler), as also is the red vision after a trauma when the eye is filled with blood, or the red tinge which sometimes comes over black print when reading with strong lateral illumination—a phenomenon which is caused by the light passing through the sclera and the blood-containing chorioid.

The nature of erythropsia has not definitely been cleared up, but it is more probably a subjective phenomenon rather than a pathological condition and depends upon induction. The earliest theories of its origin may be dismissed—the light passing through the lids and becoming coloured with blood (Snellen, Koster), and the entoptic vision of the visual purple (Fuchs). Since it is more readily produced by short-waved light and since it occurs especially after cataract extraction when that light has better access to the retina, Birch-Hirschfeld and Schanz advanced the theory that it was due to ultra-violet rays. Vogt has, however, shown that the phenomenon can be produced by light of any wave-length, that the most effective wave-lengths were 5000 to 5700 A U, that it occurred readily when the ultra-violet was filtered off, and that it could *in no circumstances* be produced in the normal eye with ultra-violet light alone. Brucke showed that the retina was normally adapted for red, and the findings of Burch have already been mentioned—that after "fatigue" of the retina, recovery comes in the order first red, then green, and lastly blue. Therefore, on stimulating with mixed (white) light, the red phase of the negative after-image will predominate (Wydler), and when the stimulating light predominates in the shorter blue and violet waves, owing to the unequal "fatigue" of the primary colour sensations, the red phase will be much more pronounced. Such an explanation will account for the partial erythropsia which occurs on unequal retinal stimulation (Purtscher) and paves the way for an explanation of the xanthopsia which so often follows it. In the cataractous eye it is the long red waves which get through the opaque lens in the highest proportion, the short blue and violet are largely dispersed, the retina in these cases is, therefore, more than usually red-adapted, and when the cataract is extracted and the retina flooded with short-waved light, an additional element—the "fatigue of disuse"—affecting the lower spectrum will further intensify the red after-image.

Apart from these physiological effects there is no evidence that incident light has any specific effect on the retina as on the other body tissues, beyond a thermic or abiotic action depending on length of wave.

Thermal Effects.—The greater part of all energy incident on the retina is absorbed by the pigment in its posterior layers and degraded into heat. Thermal lesions are, therefore, easily produced experimentally, and have been studied in animals by a large number of observers—Czerny (1867), Deutschmann (1882), Widmark (1892), Herrnheiser (1896), Aubaret (1907), Birch-Hirschfeld (1912), and Verhoeff and Bell (1916). When the lesion is on the disc there may be an intense hæmorrhagic retinitis, due to thrombosis of the central vessels. Elsewhere on the retina corresponding to the site of the image, the lesion appears as a small red spot due to chorioidal congestion, localised and sharply defined, demonstrating the necessity for the attainment of a critical temperature to effect tissue destruction. Microscopic examination shows that the greatest severity affects the pigment layer where the heat is absorbed, the cells of this layer show fragmentation and vacuolisation of the cytoplasm, and finally break up altogether and disappear leaving only the pigment. Thereafter follow in intensity the layers in order as they are affected by conduction from the pigment layer, the rods and cones, which become swollen and granular, and the chorio-capillaris where there is intense local hyperæmia, with extravasations of blood. The nuclear layers, the ganglion layer, and the nerve-fibre layer are only affected when the deeper layers are entirely disintegrated and are represented by pigment alone. Some days later the retina is seen to be entirely disorganised, or to be fixed by heat coagulation; while after some months the retina is represented locally by neuroglia containing pigment and the chorioid by a vascular fibrous tissue.

Abiotic Action.—Since only the longer ultra-violet rays can reach the retina, it would seem improbable that any marked abiotic effect could be produced; but although several observers have failed to obtain them (Czerny, Deutschmann, Ogneff, Bach, Verhoeff and Bell) definite abiotic lesions have been described by Strebel, Kiribuchi, de Ridder, and Birch-Hirschfeld. The lesion in contradistinction to that caused by heat attacks primarily the most anterior

THE PATHOLOGICAL ACTION OF LIGHT UPON THE EYE

BY W. STEWART DUKE-ELDER, B Sc,
M D St And, F R C S Eng,
PLIMMER RESEARCH FELLOW IN PATHOLOGY

(From the National Institute of Medical Research and the Ultra-Violet Clinic, Royal London Ophthalmic Hospital)

PART III *—ACTION UPON THE RETINA.

THE question of the pathological action of light upon the retina has given rise to much speculation and controversy, and even to-day our knowledge of many points can by no means be said to have passed beyond the stage of uncertainty and conjecture It is a subject which not only presents many interests in the fields of pure science and applied medicine, but is of importance industrially and from the point of view of general hygiene

1 *The Energy Incident on the Retina*

(a) *The Nature of the Light Incident on the Retina* —The nature of the light incident on the retina is determined by the transmission and absorption of all the ocular media In the upper part of the spectrum in the region of the infra-red the researches of Hartridge and Hill and Vogt have shown that above wave-lengths of 12,000 Angstrom units the energy which reaches the retina is practically negligible in quantity Thereafter the transparency increases rapidly, until at 7000, at the commencement of the visible red, 94 per cent of the incident energy is transmitted through the ocular media and falls upon the retina From this point the media may be considered transparent until the lower part of the visible spectrum is reached, here, in the ultra-violet, the commencement of absorption is determined largely by the lens the albumoid of which is the most powerful absorbent in the path of the light Spectrograms show that the dividing line here varies with that of the isolated lens, being some 200 A U above it (Brucke, Schulek, Hallauer, Shoji), absorption in quantity commences at about 4000 in the adult, and the more recent determinations indicate that light of wave-lengths as low as 3300 reaches the retina (Shoji) Apart from a considerable variation with the intensity of light used, this limit varies largely with the individual, it is raised in age and in the cataractous eye, and in the child the retina receives in appreciable quantity rays well within the limits of abiotic activity (Schanz, Graham) This considerable transparency persists for some time, thus Shoji found that in the infant the lens transmitted light of wave-lengths 3050, at 17 years 3038, and at 23 years of age 3125 The number of investigators who have examined human lenses is small, and the question cannot yet be considered as finally established, but from the information we have it would seem that the human eye is more transparent to the shorter spectrum than that of most laboratory animals It is of interest to note that in nocturnal animals, as the owl, the eye media transmit the ultra-violet down to 3000

The limits of transmission in this region of the spectrum may also be deduced from the observation of the lower limit of retinal visibility The upper end of the spectrum does not lend itself to investigation by this method, since, while the average person cannot appreciate (as red) waves longer than 7500, and the maximum limits recorded are 8350 (Helmholtz) and 8400 (Hertel), we have seen that waves of 12,000 reach the retina, 80 per cent of the infra-red energy falling upon it is in fact invisible (Vogt) There is good reason to believe, however, that all the shorter waves which can penetrate the media are appreciated visually The sensation produced has been variously described as indigo or silvery blue (Helmholtz) or silvery grey (Sekulic, Sauer), but the writer prefers to agree with Birch-Hirschfeld in describing it as a lavender grey It may be that the sensation is due to fluorescence in the retina, although the sharpness of the lines would seem to negative the suggestion; but whether it is or not, the nature of its production does not affect the point at issue Fluorescence in the lens must, however, be eliminated as thereby short waves are transformed in part into longer waves, which latter might readily reach the retina, while the former were absorbed Through neglect of thus taking the precaution of defining retina visibility as the perception of a real spectral line free from fluorescence many observers are in error (Helmholtz, Edridge-Green, &c), but the majority have put the limit with the usual intensities of illumination at about 3500 Glancy, however, who took minute precautions against fluorescence, using a very high-tension spark as source, states that although below 4000 the spectral lines appear much fainter than the spectrogram indicates, yet the 3170 line is plainly visible The limit varies with age, only 1 in 12 individuals above 50 years being able to see below 3950 (Widmark), while in those in whom the lens has been extracted the limit is lowered considerably, both in wave-length (de Chardonnet) and in visual threshold of intensity for the same wave-length (Birch-Hirschfeld).

We may take it, then, that the retina is reached by practically all the waves between 4000 and 7000 (the visibles), and by a part of those between 7000 and 12,000 (infra-red), and between 4000 and a limit varying about the region of 3200 (long ultra-violet)

(b) *Concentration of Energy at the Retina* —In its passage through the ocular media to the retina a portion of the energy incident on the eye is lost, partly by the specific absorption of the media themselves, and partly by dissipation due to their optical heterogeneity Calculating from the extensive data of Aschkinass the loss by absorption has been computed by Luckiesh to be 30 per cent of the total for sources of the nature of the usual artificial illuminants and the sun, which may be considered to be radiometrically equivalent to a black-hot body at 5000° C absolute The loss by dissipation, made up of reflected, dispersed, and aberrated rays, may be taken as 10 per cent Counteracting these two influences, the refraction of the optical system of the eye concentrates the energy to a point on the image on the retina of the emmetrope, a concentration which, when high intensities are involved, may readily produce pathological effects here while leaving the structures in the anterior eye unaffected. In contradistinction to what we have seen to obtain in the consideration of the energy distribution in the lens, since the retinal image of a large body is itself large and widely spread out, for the same total intensity of radiation, the greater the extensity of the source, the smaller the energy concentration at the retina, the main danger to the retina, therefore, lies in sources subtending a small solid angle and radiating with high intensity—e g, the sun

2 *Pathological Effects*

Pathological effects caused by light upon the retina may occur in one of three ways (1) by over-stimulation and consequent impairment of the physiological mechanism of vision, (2) by thermic action, and (3) by abiotic action

Since the infra-red rays do not excite the physiological mechanism of vision they cannot over-stimulate it Any pathological effects which the visible rays (those between 7000 and 4000 A U) may cause in the functioning of this mechanism are difficult to assess in the present state of our knowledge, and the old conception of retinal "fatigue" as used by Helmholtz and the earlier writers requires modification When the dark adapted eye is exposed to light, the light induces a new mechanism of functioning—photopic vision There is evidence that moderate exposure to bright light increases the retinal excitreadily develop, if, however, the lens remains transparent, the actinic rays pass through, and are thus able to exert a harmful effect on the retina Gjessing has recently confirmed van der Hoeve's statistics, but although it may be considered as probably established that the two diseases do not often occur together, statistical evidence of this kind is, when taken by itself, somewhat unconvincing, and very often lends itself to misinterpretation The most that can be said at the present time is that the matter is still open, and the theory certainly unproven

---

* Parts I and II appeared in THE LANCET of June 12th, 19th, and 26th respectively

Industrially, while all intense illuminants give rise to the subjective symptoms already mentioned, the cases of actual retinal injury are rare After exposure to arc lights and in electric welding diminution of vision, contraction of the visual field, and scotomata are relatively common, while erythropsia and xanthopsia occur more rarely, objectively there have been reported œdema of the retina (Little), pallor of the disc (Valois), and macular changes (Lubinski) These findings are, however, exceptional, and the naked arc can be fixed for several minutes without any damage being done to the retina beyond temporary impairment and derangement of vision The flash of the short-circuiting of a high-tension current almost always gives rise to the characteristic visual disturbances, which are usually temporary, but on occasion have remained over indefinitely long periods of time; haziness of the disc margins (Terrien) and macular (Haab) and chorio-retinal changes (Uhthoff, Kramer, Bettremieu Knapp) have been described These latter appear as small pigmented areas, and are without doubt the cicatrices of thermal lesions caused by the longer wave-lengths of the very wide range of radiations emitted by these sources Similar thermic retinal lesions after exposure to a lightning flash have been reported by Le Roux and Renaud and Oliver

OBSERVATIONS ON CHOLECYSTOGRAPHY.

BY T IZOD BENNETT, M D, M R C P LOND,
ASSISTANT PHYSICIAN, MIDDLESEX HOSPITAL, PHYSICIAN TO THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL,

ALAN MONCRIEFF, M D, M R C P LOND,
MEDICAL REGISTRAR, MIDDLESEX HOSPITAL,

AND

F. G NICHOLAS, M B, B S LOND,
D M R E CAMB,
ASSISTANT RADIOLOGIST, MIDDLESEX HOSPITAL.

(*From the Departments of Physiology and Radiology and the Bland-Sutton Institute of Pathology, Middlesex Hospital*)

THE introduction of tetra-halogen compounds of phenolphthalein has made it possible to obtain useful data concerning the functions of the liver and biliary tract, both in health and disease.

As is well known, these compounds have been used in two ways (1) Tetrachlorphenolphthalein has been administered intravenously and the rate of its elimination into the bile has been utilised as a measure of the functional capacity of the liver (2) The tetrabrom and tetraiodo compounds have been administered either intravenously or orally, and the subsequent opacity of the gall-bladder has been utilised for studying the size, appearance, and possible distortion of that organ

One of us (T I B) has made a series of experiments with a view to determining whether these two types of observation could not be made simultaneously. Samples of various compounds have been administered both orally and intravenously to guinea-pigs and to rabbits, but it has been found that, whereas the tetrachlor compound is a dye which colours the blood serum sufficiently to make estimations of its concentration easy, the tetraiodo and tetrabrom compounds produce no such marked effect

Conversely, the relatively low atomic weight of the tetrachlor compound makes it useless for radiographic purposes and even by radiograms of recently removed livers from animals to whom it has been administered in full doses no X ray shadows of the gall-bladder or bile-ducts were obtained In these circumstances, we decided to postpone attempts to study series of phenomena simultaneously and concentrated our attention on cholecystography.

The toxicity of these substances to the tissues is reported to have led to the production of sloughing, when even a few drops have escaped locally during intravenous injection The risks of such accidents are not great, but, as the test is a diagnostic one only, the possibility of such an occurrence makes the oral method of administration greatly preferable We have therefore confined our study to the oral

layers Chromatolysis and vacuole formation has been described in the ganglion cells, and loss of chromatin in both nuclear layers, while the deeper layers are unaffected ; Mettey has described atrophic changes in the optic nerve The changes observed by the writer have always been very slight, so slight as to seem within the physiological variation of the normal rabbit's retina after being subjected to cutting and staining The exposures given were, however, never more than 30 minutes duration, while Birch-Hirschfeld, who has described these lesions most confidently, subjected his animals to radiations lasting for periods up to six hours This difficulty in producing abiotic pathological changes here agrees with the negative findings of Verhoeff and Bell, who experimented on monkeys, and in one case on a woman the day before excision of the eye for carcinoma of the lid It seems reasonably certain, therefore, that the retina is adequately protected by the ocular media from abiotic rays under all ordinary circumstances; but it is probable that extreme exposures for long periods may injure it, and the possibility of ultimate damage from exposures of less extreme intensity but over periods lasting many years is not without the bounds of possibility The above pathological changes are obtained much more readily and to a much more marked degree in the lensless eye, experimentally they are produced in the aphakic rabbit after exposures which leave the retina of the normal animal unaffected (Birch-Hirschfeld, Schulek)

Clinical Occurrence of Retinal Lesions

Sun Blindness —Visual disturbances from looking at the sun have been known and recognised for a very long time Plato refers to them in his Phaedo ; Galileo, looking at the sun with his telescope, injured his eyes, and Galen describes the symptoms in De usu Partium Reid, in 1761, appears to have recorded the first clinical description, and Dufour, in 1882, was the first to describe accurately the ophthalmoscopic appearances of the lesions

The sun may be considered from the radiometric point of view as a black-hot body at 5000° C absolute, and the energy available in its radiations has been computed to be about 1,000,000 erg-secs per sq cm at the earth's surface (Verhoeff and Bell) If the pupil is strongly contracted to about 2 mm , as it would be on observing it directly, about 3 per cent of this energy will enter the eye, and since slightly over 30 per cent of that entering is lost in its passage through the eye, the energy available at the retina will be of the order of 20,000 erg-secs per sq cm , if the size of the image is 0 15 mm , this will entail a concentration of energy here of the order of 113,000,000 erg-secs per sq cm —quite enough to produce a severe lesion in a very short time Ordinarily, when we look at the sun directly we are only protected from injury by the fleeting duration of the glance, and by the great lack of fixation which distributes the energy accumulation at any one part of the retina ; only on unusually determined fixation is injury sustained Every eclipse has brought to light a number of such cases, and the name " eclipse blindness " usually applied to the condition is, therefore, appropriate

The greater part of the infra-red in the solar spectrum is absorbed by the moisture of the atmosphere, and the ultra-violet moiety of the total energy reaching the earth is comparatively small Experimentally, the typical lesions of eclipse blindness have been produced by filtering out the infra-red by a layer of water (Deutschmann) or of a solution of ferrous sulphate which is strongly adiathermic, and also by eliminating the ultra-violet below 4000 by the interposition of Schott's heavy flint glass ; while uviol glass, which obstructs the visibles but allows the passage of ultra-violet affords complete protection (Best) The lesion is therefore due mainly to the luminous waves It is to be remembered that the maximum of the solar energy intensity is near the shorter visibles in the blue-green (4700–5000 A U), and that therefore where the sun is the source, the greatest energy intensity, and therefore the greatest heat effect, is produced by these rays

The lesion is a purely thermal effect, corresponding to that already described as obtained experimentally The subjective symptoms are a diminution of visual acuity, sometimes to 6/60 or less, but usually to about the level 6/12 , the perception of a diffuse cloud before the eyes, which often shows rotatory movements and may be worse in bright light , a scotoma , and often metamorphopsia The scotoma is central, is usually absolute but often relative, or may be initially absolute and later become relative, or absolute centrally surrounded by a ring zone of a relative nature , it does not accurately correspond to the image of the sun owing to the lack of fixation spreading the affected area irregularly , in some weeks it tends to contract, but it often is persistent Erythropsia occurs rarely Ophthalmoscopically, there is originally a small red spot at the macula due to choroidal congestion, which may be accompanied by general hyperæmia, œdema, and hæmorrhages Small irregular pigment spots frequently remain at the macula, indicating definite and permanent destructive lesions, while macular holes have been observed (Lasarev) Rare complications are obstruction of the central vessels (Batten, Walker), hæmorrhagic retinitis (Leber, Bokenham), retrobulbar neuritis (Collins, Menacho), and optic atrophy (Ulbrich)

Similar symptoms with similar retinal changes have been described as occurring in a milder form in bright weather when the sun is not directly regarded, as the case reported by Lawson wherein they developed after a day's golf and were followed by permanent fine macular spots Dark people are more susceptible than fair, owing to the larger amount of absorbing pigment in the former, while hypermetropes show a much higher incidence in the literature than those of normal or myopic refraction The concentrating effect of strong convex spectacles in the hypermetrope may predispose to injury, and symptoms have been reported after the prolonged use of field glasses on a sunny day (Lawson)

Whether or not prolonged exposures to light lasting over years have an injurious effect on the retina by a cumulative action is an open question, and one which, by its nature, is very difficult to answer with any degree of certainty It is improbable that any such effect could be due to a thermal lesion, as is eclipse blindness, for at any one time a critical temperature must be attained to produce any destructive effect, and with intermittent exposures the temperature effect is nullified in the intervals of cooling, and a cumulative action, therefore, cannot be obtained Diffuse daylight and all ordinary illuminants, therefore, can have no ultimate thermal effect on the retina With the short rays, however, the case is different, since the latent period of abiotic action extends up to about 24 hours, and a cumulative action can therefore be produced by exposures on successive days even although separated by intervals of sleep We have seen that the experimental production of such lesions is very difficult, owing to the high degree to which these rays are absorbed in the media of the eye before they can reach the retina, but the factor of small amounts of damage accruing over many years is certainly one to be considered Thus, accompanying the photophthalmic symptoms met with in snow-fields, Widmark records the occurrence of amblyopia, and Birch-Hirschfeld a scotoma for red and green, and ophthalmoscopically a hyperæmia of the retina and disc may occur (Reich) Van der Hoeve has suggested that ordinary daylight, acting less intensively, and over indefinitely long periods of time, may be the cause of senile macular degeneration His thesis is based largely on the evidence that his statistical studies show that this retinal disease appears in its incidence to be antagonistic to cataract , the short waves of light (he argues) cause cataract by impairing the nutrition of the lens through an indirect effect on the ciliary body, and the lens having become less transparent, the retina is protected from the short wave-lengths, and macular degeneration does not there should, in the second film, be a distinct diminution in this size with an increase of density due to concentration of contents and contraction of the walls of the gall-bladder, which are the normal functions of the non-infected organ.

7. It is the custom of many American observers, in all cases of doubt, to follow the oral administration with an intravenous one. If a non-toxic compound can be introduced this will undoubtedly be an improvement. At present the oral method by itself is very satisfactory in the great majority of cases: it is easy and safe and we have experienced no difficulty in employing it both for out-patients and in-patients. Vomiting occurred in three cases only, slight regurgitation in two others, and trivial nausea in one or two. In no case were any toxic symptoms observed.

Our thanks are due to those physicians and surgeons who submitted cases for investigation: we have also had most useful help from Messrs. Allen and Hanburys in the preparation of the capsules. The expenses of one of us (T. I. B.) were partly defrayed by a Government grant made on the recommendation of the Royal Society.

This paper forms a part of a report to the Medical Research Council.

Clinical and Laboratory Notes.

A CASE OF
MEASLES SHOWING UNUSUAL NERVOUS SYMPTOMS.

BY J. TODESCO, M.D., M.R.C.S., L.R.C.P., D.P.H.,
RESIDENT MEDICAL SUPERINTENDENT, BOROUGH HOSPITAL, CROYDON.

THE following case of measles showing unusual nervous symptoms appears worthy of record.

J. W., a boy aged 6½ years, was admitted to the Borough Hospital on the morning of Jan. 18th, 1926, in a semi-conscious state. About a week previously he had developed signs of a cold in the head with fever and coughing, a typical measles rash appearing four days later. The night before admission he was noticed to be sleeping heavily, could be roused with difficulty, and appeared semi-conscious. He had been quite well prior to his present illness, was intelligent, and had never suffered from fits; there was no history of epilepsy in the family.

On admission he was very irritable, crying out from time to time, could not answer questions and resented examination, being roused with difficulty. The face was flushed, the mouth very sore, and tongue dry and coated. Respirations were increased, but no adventitious signs elicited in chest, the heart action being rapid and weak, temperature 101.6° F. General mottling of the skin was observed, due to a faded measles rash. The pupils were large, equal, and fixed, with slight conjunctivitis: no rigidity of neck or limbs was present: the knee-jerks were normal, but no plantar reflex was obtained, though a bilateral Kernig's sign was noted. He had marked difficulty in swallowing and obstinate constipation.

On the afternoon of admission the boy had five fits, lasting between 10 and 15 minutes. During these he became very cyanosed, ground his teeth and had twitchings of right side of face, right arm and leg, whilst the left side of the body was held rigid. He was incontinent both of urine and fæces; the pupils were dilated and fixed. After each fit there was general muscular relaxation, the patient lying curled up in bed crying out and becoming very restless from time to time. At 6 P.M. he vomited some brownish fluid. On lumbar puncture, performed on the morning of admission, the cerebro-spinal fluid was under slightly increased pressure and slightly turbid. On examination it did not reduce Fehling's solution; there was marked increase of polymorphonuclear cells; no bacteria seen; the fluid remained sterile on culture. The boy was very restless and moaning during the night of Jan. 18th, having two further similar seizures between 10 P.M. and 4 A.M., with incontinence both during and after them. On the morning of Jan. 19th he appeared more conscious, though unable to speak or answer questions and resenting examination. He was very restless and cried out from time to time. Temperature was 99.8°, his colour still poor. In the evening he became quieter, could swallow more easily, and answer questions: his pupils were equal, reacting to light and accommodation, and he appeared quite conscious.

From this time onwards the boy's condition steadily improved. He had no further seizures, but still resented examination, being disinclined to speak or take food and being incontinent at times. He was still restless at night. His temperature became normal on Jan. 21st, remaining down subsequently. By Jan. 24th he was convalescent, but appeared very emotional, mentally dull and dazed at times. He got up for the first time on Feb. 1st, being still dull, and hesitating when answering questions. He had no recollection of being brought to hospital or what had happened during his stay there. He was discharged on Feb. 9th.

The points of interest in this case are the nervous complications with marked meningeal symptoms, fits, and Kernig's signs, all very uncommon in measles. In meningism occurring in the course of acute specific fevers Kernig's sign is usually absent, and the cerebro-spinal fluid, though it may be under pressure, does not show an excess of cells as occurred in this case. The character of the cerebro-spinal fluid obtained was similar to that seen in acute meningitis, but unlike this disease, there was rapid improvement with loss of meningeal symptoms within 48 hours of their onset, the temperature never rising above 100° except on the day of admission, and coming down to normal after four days.

I wish to thank Dr. H. P. Newsholme, medical officer of health for Croydon, for permission to publish this case.

A CASE OF RENAL CALCULUS.

BY A. C. SEN GUPTA, M.B.,
CHIEF MEDICAL OFFICER, SARANGARH STATE, C.P., INDIA.

THIS case seems to be interesting in that so large a number of stones was removed so successfully, under most difficult circumstances, in a moffussil dispensary.

The patient was admitted in the branch dispensary of this State under a sub-assistant surgeon. There was an abscess in the right lumbar region. The doctor, thinking it to be a simple abscess, opened it and during the discharge of pus he detected to his astonishment two stones coming out. He dressed the case for about a fortnight, but finding no improvement sent the patient to me at the main hospital of this State. I diagnosed it to be a case of perinephric abscess secondary to renal calculus.

I tried to dissect out the kidney by the lumbar route. After the usual skin incision, I found the surrounding fascia and muscles so adherent that it was not possible to separate them from each other. I followed the sinuses formed by the passage of the stones and, working with my finger, I reached the stone cavity in the kidney, gradually removing all the sloughs and decomposed tissues on the way. I found there were two sinuses joining the kidney cavity, one reaching from the surface straight down to the kidney and the other taking a curve upwards and outwards and then a little forwards, thus reaching the kidney. There were two stones at the mouth of each sinus. In the first one there was a large branched calculus firmly held in the calyces of the pelvis. I loosened the stone in its bed by passing my index-finger all round it and delivered it with a stone forceps just as the head of a child is delivered by midwifery forceps, because there was very little space to work out the stone forceps. After its removal 14 more stones were delivered by the index-finger. The stone occupying the mouth of the other sinus was also fairly big and took about an hour to remove with the finger, as the curvature of the sinus was such that no forceps could work, neither could the wound be enlarged without unnecessarily cutting the muscles in several directions.

In all 18 stones were removed from this patient. For the last three months he has been in the hospital, the sinuses are almost filled up now, and the patient's health has much improved, though he still complains of a little pain over the upper pole of the right kidney.

method, and are able to confirm the favourable reports published by other observers

At the outset we tested a series of samples from various sources, both of tetrabromphenolphthalein and tetraiodophenolphthalein, but whether owing to their chemical composition or to the manner in which they were supplied for use (gelatin capsules, &c) our results were uniformly negative Finally, we secured a supply of the tetraiodo compound prepared in America by the Malinkrodt Chemical Works under the name of iodeikon With this we have had good results

Method

The patient is prepared as for an ordinary skiagram of the gall-bladder An ounce of castor oil is given on one night and ½ oz the next night On the following day a light breakfast and a very light lunch are permitted and an ordinary skiagram of the gall-bladder taken in the afternoon Tea and bread-and-butter are permitted on the same day, and at 12 midnight another small meal is taken, during which the capsules of iodeikon are swallowed On the following morning the patient has a cup of tea only for breakfast and is X rayed at 10 A M, 2 30 P M., and 4 30 P M This scheme has been gradually evolved to suit all parties concerned The dose of dye employed has usually been 5 g, although, if the patient weighs under 100 lb, this is reduced to 4 g It is given in capsules each containing ½ g

At the outset of our investigations difficulties were encountered owing to the methods in which the capsules were prepared If a readily digested covering, such as gelatin is used in a large proportion of cases the dye is liberated in the stomach, an insoluble hydrochloride is then formed and vomiting usually follows, practically the whole of the dye being thus rejected If, on the other hand salol is employed, the pills are often so resistant to digestion that they may pass through the cæcum, and in consequence, no absorption of dye occurs

Success depends upon the liberation of the dye in the upper part of the small intestine, but not in the stomach, and it appears clear that, as there is considerable variation in the strength of the gastric and pancreatic digestive juices in different individuals, it is almost impossible to devise a capsule which will not be too readily digested by some and too resistant to the digestive juices of others

With the assistance of Messrs Allen and Hanburys, we finally secured a formalised gelatin capsule which has given almost uniformly successful results, it must be freshly prepared, however, because, if kept more than 24 hours, it becomes too tough for proper digestion

Analysis of Fifty-eight Cases of Cholecystography

Cases 1–4 inclusive were given sodium tetrabromphenolphthalein in cachets No results were obtained The remaining 5–58 inclusive were given sodium tetraiodophenolphthalein, mostly in formalised gelatin capsules In a few cases salol-coated pills were used

Results

1 *Normal gall-bladder shadows obtained after giving dye* Twelve cases Of these, ten were not operated upon, and were either in the nature of control cases, or else the test was used to exclude disease of the gall-bladder, while, in the remaining two cases, operation or autopsy confirmed the normal state of the gall-bladder

2 *Faint shadows of gall-bladder obtained after giving dye* Ten cases Of these, in two cases a pathological gall-bladder was found at operation, a normal gall-bladder in one case, in one case vomiting had occurred soon after giving the dye, and in six cases no operation has been performed Many of these cases came early in the series, before the importance of having freshly prepared capsules was realised

3 *Mottled shadows of gall-bladder obtained after giving dye* Three cases In all three cases a pathological gall-bladder containing stones was found at operation

4 *No shadow of gall-bladder obtained and no evidence of unabsorbed dye* Twenty cases Of these cases, in four a stone was found at operation to be blocking the cystic duct, in another six the gall-bladder was pathological and contained stones, in three cases there was disease of the duodenum near the ampulla of Vater (ulcer and malignant disease), while in the remaining seven cases two vomited severely after receiving the dye and in five no operation has been performed

5 *No shadow of gall-bladder obtained, but unabsorbed dye seen in the alimentary canal* Five cases

The remaining four cases of the 54 in this series are accounted for as follows Two are awaiting operation One patient was very neurotic and unable to swallow the capsules One of the cases represents a repeat, and is included only once

Summary and Conclusions

From the results here analysed the following points emerge —

1 The importance of taking a skiagram before the administration of the dye has not hitherto been sufficiently emphasised In the first place it must be remembered that the gall-bladder may give a definite shadow in this preliminary plate If, after administration of the dye, there is no increase in the density of this shadow, it is evidence that no dye has entered the gall-bladder, a deduction which would not have been possible without the preliminary skiagram

2 If there is some pathological condition present, not, however, amounting to complete obstruction of the cystic duct, the opacity caused by a limited amount of dye entering the gall-bladder, plus the original density caused by the gall-bladder itself, if such has been found in the preliminary skiagram, may give the appearance of the opaque shadow of the normal cholecystogram

3 Certain other shadows, such as those of renal calculi, calcified glands, or areas of calcification in the costal cartilages, may also be present and are less likely to lead to erroneous deductions if seen clearly in the preliminary plate

4 When definite gall-stone shadows are seen before the administration of the dye there is no need to continue with cholecystography But if certain vague shadows in the preliminary plate are seen to coincide in position with a patchy gall-bladder shadow after administration of the dye, it is strong confirmatory evidence of their nature

5 It is most important to observe the alimentary canal, and especially the cæcum, for evidence of unabsorbed dye If this is not found and the gall-bladder does not fill up with dye, it is a fair assumption that there is some pathological condition of the gall-bladder or ducts present In one case of duodenal ulcer with pyloric stenosis, the capsules were all held up in the stomach where a dense shadow of conglomerated capsules could be seen The dye was obviously not absorbed, and hence absence of a gall-bladder shadow in this case was of no significance The importance of securing proper absorption of the dye cannot be over-estimated, because the first postulate of the method is that *a negative result implies gross disease of the gall-bladder*, and, if this negative result is due to failure of absorption following imperfect technique, most serious errors may result The only possible exception to this rule occurs when there is present advanced and widespread disease of the liver In one of our cases no gall-bladder shadow was obtained and no unabsorbed dye could be seen in any part of the alimentary canal At autopsy a few weeks later the gall-bladder and ducts were found to be normal, but there was very advanced cirrhosis of the liver

6 In examining the shadows of the gall-bladder, attention should be given to the variations in size and density on the series of films A healthy gall-bladder may cast a surprisingly large shadow, but

Reviews and Notices of Books.

A MANUAL OF THE PARASITIC PROTOZOA OF MAN

By CHARLES F. CRAIG, M.D , M.A. Hon Lieut - Colonel, Medical Corps U.S Army, D S M London: J. B. Lippincott Company. 1926 Pp 569 35s.

THE rapid advances which have been made during recent years in our knowledge of the protozoan parasites of man and the diseases they cause have led to a realisation of the fact that it is essential for every medical practitioner, no matter whether he is domiciled in the tropics in temperate or even in cold climates, to be able to diagnose with a fair degree of certainty each and every species inimical to human well-being In our medical schools greater stress is being laid on the teaching of this subject, but in this both teachers and students have been sadly handicapped by the lack of up-to-date and reliable text-books Since the war several excellent monographs have appeared, dealing, however, only with parts of the field, and also a few text-books; the former were more in the nature of zoological treatises, while the latter contained much that was irrelevant and did not emphasise the practical points so vital to the medical man

To produce a work for medical students and practitioners, laboratory and research students which would fill this want by adequately covering the salient features of the morphology, life-history, relation to disease, and prophylaxis of these parasites was the main object of the author in compiling his text-book. His manner of approach is an excellent one, and most methodical After a general consideration of each group the individuals of that group are dealt with in detail Thus a list of synonyms is given subsequent history and nomenclature are discussed, and this is followed by a clear and lucid description of the morphological characters both as found in fresh and also in stained preparations The life-cycle, method of reproduction, transmission, and mode of infection of the vertebrate host are all clearly set forth, while such points as the possibility of cultivating the organism in question or of producing infections experimentally in laboratory animals receive full mention. A section is devoted to the relationship which the parasite bears to the causation of symptoms of disease in man

In startling contradistinction to the lucidity of the text is the way in which the illustrations have been prepared. The pictorial reproduction of the parasites is surely as important, if not considerably more so than the written word That the student should be able at a glance to compare his microscopical findings with an accurate drawing is as must be obvious to all who have had either to learn or to teach the subject one of the first essentials, and from this aspect the book falls sadly short of the necessary standard of excellence A wide use has been made of photomicrographs the majority of which are splendid examples of the photographer's art as applied to the microscope, but it must be remembered that the possibilities are limited in this direction that only one focal plane containing perhaps a few of the main features can be registered and even then the reproduction cannot be so sharp as the visual image Thus for example in some of the photographs of the amœbæ the nuclei are moderately sharp and clear, while the cytoplasm or body substance after all as important as the nuclear structure is a meaningless shadow The interpretation of a photomicrograph and its appreciation are matters for those already expert and not for students With a few exceptions the illustrations, other than photomicrographs have been taken from the works of other observers Some of these reproductions do not appear to be as clear as the originals while the combining of drawings from two or more sources has resulted in fusion products which also do not appear to do justice to the original pictures. The value of a subsequent edition would be greatly enhanced by the inclusion of original drawings of microscopic appearances

Where it has been necessary in the text to indicate that a certain matter is still sub judice, or that disagreement exists in the interpretation of certain phenomena, the author has endeavoured to state both sides of the question fairly and without bias For example he quotes the classifications of the amœbæ in man according to Dobell and Stiles and Boeck, is in complete agreement with neither, and finally gives a classification according to his own views Indeed, it may be said that only in the case of *Craigia hominis* not yet accepted as a true parasite of man by the majority of European, and more particularly British workers, does any suggestion of partisanship become evident, and, as this was described in the first instance by Craig himself, has been accepted by such authorities as Kofoid and Swezy, but has been rejected by others on what Craig considers to be inadequate evidence his attitude on this question is only natural Generally speaking, the author's teaching is in accord with the bulk of modern scientific opinion, and there are no large departures from the orthodox We note however, that he separates the parasite of æstivo-autumnal or malignant tertian malaria into two subspecies, *Plasmodium falciparum* and *P. falciparum quotidianum* Again, in this section on malaria his use of certain expressions might conceivably give rise to confusion The term spore should not be applied to the products of asexual multiplication—the merozoites—nor should gamete and gametocyte be used interchangeably Sporulation, too, although used for many years now to indicate the final stages of the asexual cycle in man or schizogony, would be better applied to the formation of the sporozoites in the mosquito

At the end of each chapter the author has given a list of references of the more important papers dealing with the subjects covered in that section. This list is not intended to be a complete bibliography; it contains more especially the recent work, and should be regarded by the student as an introduction to the literature. Another most useful feature is the technical appendix, in which is included the more important laboratory methods of cultivating or preparing permanent stained preparations of the parasitic protozoa.

We have no hesitation in recommending this book to the medical practitioner or the medical scientist as one of the best accounts of this important branch of medicine in English. One or two important additions might be made with advantage. The absence in the present volume of coloured plates showing the malarial parasites at all stages of development, and of the trypanosomes and allied flagellates, is noticeable. The number of original diagrams illustrating life-cycles should be increased and those already included should be carefully revised. There would seem little doubt that a demand for a second edition will give the author early opportunity to make these improvements

---

NUTRITION.

Troubles des Échanges Nutritifs By C ACHARD, Professeur de Clinique Medicale à la Faculté de Médecine de Paris Membre de l'Académie de Medecine. Paris: Masson et Cie 1926 Two vols Pp. 1220. Fr.110.

IN these handsome volumes Prof. Achard has adopted a new classification for the discussion of dietetics and all those diseases which chiefly affect nutrition. Physiology is his basis and he considers in sequence all methods by which the body can ingest gases water, mineral matter carbohydrates fats and lipoids and lastly nitrogenous substances. "L'esprit gaulois' says one of Meredith's characters, "sparkles with the clear crystal of common sense," and in choosing this classification Prof. Achard has not only been able to display his facts in logical sequence, but has succeeded in approaching nearer

FRACTURE OF THE ANATOMICAL NECK OF HUMERUS WITHOUT APPARENT DIRECT VIOLENCE

By F Milnes Blumer, M B, C M Edin,
SENIOR HONORARY SURGEON, STAFFORDSHIRE GENERAL INFIRMARY

The patient, a farmer, aged 38, dislocated his right shoulder some six or seven years ago while in an epileptic fit I reduced it, and the normal function of the joint was regained On Jan 19th, 1921, I received a message to say he had again put his shoulder out On reaching the house I found him lying on his back on the floor His wife told me that, feeling a fit coming on, he promptly lay down As the fit developed he stretched his arms straight down by his side with his muscles in tense contraction The wife said she then heard a click, which told her he had again dislocated his shoulder The patient, she insisted, never fell but had lain down quickly, as was his custom, and received no blow of any kind As the joint appeared to be dislocated, I proceeded to reduce it under chloroform, and on manipulating it I felt crepitus, and could not completely correct the deformity Examination under X rays two days afterwards revealed fracture of the anatomical neck This was confirmed when I operated a week later and removed the fragments, which were loose within the capsule There was no injury to the glenoid The wife is an observant and intelligent woman, and her statement that there was no direct violence can be accepted How, then, was the fracture caused?

The patient has now a good range of movement at his shoulder, and is able to do all his work

Medical Societies.

RESEARCH DEFENCE SOCIETY

ADDRESS BY DR J A MURRAY

The annual meeting of this Society was held on June 25th at the rooms of the Medical Society of London, Lord Lamington, the President, occupying the chair

The President referred to the sense of loss and sorrow felt by those responsible for carrying on the Society's work at the death of Mr Stephen Paget The Society owed its inception entirely to Mr Paget, and it was he who had safeguarded its interests during difficult times

Lord Knutsford said that this was the first meeting the Society had ever held without the presence of Mr Paget Although sometimes misrepresented by those who opposed him, Paget's activities were due not to a love of controversy, but to his hatred of everything which savoured of untruth and misrepresentation The committee had decided to establish a Stephen Paget Lectureship at various universities and seats of learning, and it was hoped to send a good speaker, every year or every second year, to different centres in memory of his work

At the end of the business meeting Dr J A Murray gave an address on the

Experimental Attack on Cancer Problems

The experimental study of cancer, he said, was started 25 years ago, and its progress could be conveniently divided into three periods The first embraced the work of Jensen and Borrel on transplantation of animal tumours, the second was that in which Fibiger, Yamagiwa and others produced cancer de novo in normal animals, while the third period was that in which the possibility of a microbic origin was worked at by Peyton Rous, Blumenthal, Gye, and Barnard

Jensen and Borrel, he said, showed that cancerous growths in tame white mice could be propagated in series in normal animals of the same kind by introducing fragments of the original growth under the skin, and Bashford showed that cancer in mice presented all the features of the malignant new growth of man and the larger domestic animals, features also reproduced in the course of the propagated tumours obtained by transplantation It became evident that the cancer cell behaved as it did because of differences inherent in it or permanently imposed on it, not because of constitutional peculiarities of the individual in which the growth had arisen. Jensen found that animals in which a first transplantation had failed were resistant to a second grafting Lumsden had recently shown that a serum against rat sarcoma could be produced in the rabbit, and under certain conditions this serum was found to have a curative action

Dealing with the second of his periods, Dr Murray referred to the forms of cancer which followed long-continued irritation Prof Yamagiwa, of Tokyo, painted rabbits' ears with tar week after week for long periods, and in some instances growths resulted which continued to grow after the tarring had been discontinued, and in a few of these cases metastases were observed in lymph-nodes These growths produced by tarring in mice were true cancers, in every way similar to classical examples on the lip and tongue of man An inevitable conclusion from the research was that the irritant did not produce cancer directly It had been suggested that loss of nervous control predisposed to cancer, but Cramer showed that tarring took longer to produce cancer on a denervated skin area than on a normal area, and the time difference was practically that which the nerves required to grow again It was usually more difficult to produce a second tar cancer than a first one

In the observations falling into the third period the claim was made that the cancerous change was produced directly, without any intermediate preparatory phase This period of work commenced 15 years ago with Peyton Rous's discovery of a sarcoma of the domestic fowl which could be transplanted to normal fowls by grafting Extracts of this tumour when freed from cells by filtration through porcelain candles which retained visible microbes, gave rise to the identical tumour when injected into normal birds, and drying the material did not prevent the transference of the tumour The fact that this tumour bred true, even when produced without living cells, and its behaviour, led to the view that its transmissibility was associated with the entrance into the body of an ultra-microscopic microbe All attempts to cultivate the virus in artificial media failed, and the infective material soon lost its power to produce a tumour when incubated at the temperature of the body Gye claimed, last year, that the loss of infectivity of the cell and bacteria-free filtrate on incubation were not due to death of the ultra-microscopic microbe, but to the destruction of an accessory chemical factor The microbe was responsible for the proliferative characters, while the specificity depended on chemical changes in the cell which permitted infection This, Dr Murray said, was the first time a microbic hypothesis of cancer had been presented in a form which was compatible with the known facts of cancer structure and behaviour He did not believe there were any other means than the experimental of solving the cancer problem

---

Extension of St Mary's Hospital, Paddington A fund of £50,000 is being raised to provide two new operating theatres and 46 additional beds, of which 13 are to be reserved for cases of accident and sudden emergency This is one of the conditions upon which King Edward's Fund has made a grant of £4000 Last year more than 1000 cases which, in the opinion of the medical officers, required urgent in-patient treatment had to be refused admission The main operating theatre is described as "*quite out of date*" and lacking in essential equipment

Reviews and Notices of Books.

A MANUAL OF THE PARASITIC PROTOZOA OF MAN

By CHARLES F. CRAIG, M D, M.A. Hon, Lieut-Colonel, Medical Corps, U S Army, D S M
London: J B Lippincott Company 1926
Pp 569 35*s*

THE rapid advances which have been made during recent years in our knowledge of the protozoan parasites of man and the diseases they cause have led to a realisation of the fact that it is essential for every medical practitioner, no matter whether he is domiciled in the tropics in temperate or even in cold climates, to be able to diagnose with a fair degree of certainty each and every species inimical to human well-being In our medical schools greater stress is being laid on the teaching of this subject, but in this both teachers and students have been sadly handicapped by the lack of up-to-date and reliable text-books Since the war several excellent monographs have appeared, dealing, however, only with parts of the field, and also a few text-books; the former were more in the nature of zoological treatises, while the latter contained much that was irrelevant and did not emphasise the practical points so vital to the medical man

To produce a work for medical students and practitioners, laboratory and research students, which would fill this want by adequately covering the salient features of the morphology, life-history relation to disease, and prophylaxis of these parasites was the main object of the author in compiling his text-book His manner of approach is an excellent one, and most methodical After a general consideration of each group the individuals of that group are dealt with in detail Thus a list of synonyms is given, subsequent history and nomenclature are discussed, and this is followed by a clear and lucid description of the morphological characters both as found in fresh and also in stained preparations The life-cycle, method of reproduction, transmission, and mode of infection of the vertebrate host are all clearly set forth, while such points as the possibility of cultivating the organism in question or of producing infections experimentally in laboratory animals receive full mention A section is devoted to the relationship which the parasite bears to the causation of symptoms of disease in man

In startling contradistinction to the lucidity of the text is the way in which the illustrations have been prepared The pictorial reproduction of the parasites is surely as important, if not considerably more so, than the written word That the student should be able at a glance to compare his microscopical findings with an accurate drawing is, as must be obvious to all who have had either to learn or to teach the subject one of the first essentials, and from this aspect the book falls sadly short of the necessary standard of excellence A wide use has been made of photomicrographs the majority of which are splendid examples of the photographer's art as applied to the microscope, but it must be remembered that the possibilities are limited in this direction, that only one focal plane containing, perhaps, a few of the main features can be registered and even then the reproduction cannot be so sharp as the visual image Thus for example, in some of the photographs of the amœbæ the nuclei are moderately sharp and clear, while the cytoplasm or body substance after all as important as the nuclear structure, is a meaningless shadow The interpretation of a photomicrograph and its appreciation are matters for those already expert and not for students With a few exceptions the illustrations, other than photomicrographs have been taken from the works of other observers Some of these reproductions do not appear to be as clear as the originals while the combining of drawings from two or more sources has resulted in fusion products which also do not appear to do justice to the original pictures The value of a subsequent edition would be greatly enhanced by the inclusion of original drawings of microscopic appearances

Where it has been necessary in the text to indicate that a certain matter is still sub judice, or that disagreement exists in the interpretation of certain phenomena, the author has endeavoured to state both sides of the question fairly and without bias For example, he quotes the classifications of the amœbæ in man according to Dobell and Stiles and Boeck, is in complete agreement with neither, and finally gives a classification according to his own views. Indeed, it may be said that only in the case of *Craigia hominis*, not yet accepted as a true parasite of man by the majority of European, and more particularly British workers, does any suggestion of partisanship become evident, and, as this was described in the first instance by Craig himself, has been accepted by such authorities as Kofoid and Swezy, but has been rejected by others on what Craig considers to be inadequate evidence, his attitude on this question is only natural Generally speaking the author's teaching is in accord with the bulk of modern scientific opinion, and there are no large departures from the orthodox. We note, however, that he separates the parasite of æstivo-autumnal or malignant tertian malaria into two subspecies, *Plasmodium falciparum* and *P falciparum quotidianum* Again in this section on malaria his use of certain expressions might conceivably give rise to confusion The term spore should not be applied to the products of asexual multiplication—the merozoites—nor should gamete and gametocyte be used interchangeably. Sporulation, too, although used for many years now to indicate the final stages of the asexual cycle in man or schizogony, would be better applied to the formation of the sporozoites in the mosquito

At the end of each chapter the author has given a list of references of the more important papers dealing with the subjects covered in that section This list is not intended to be a complete bibliography; it contains more especially the recent work, and should be regarded by the student as an introduction to the literature Another most useful feature is the technical appendix, in which is included the more important laboratory methods of cultivating or preparing permanent stained preparations of the parasitic protozoa

We have no hesitation in recommending this book to the medical practitioner or the medical scientist as one of the best accounts of this important branch of medicine in English One or two important additions might be made with advantage The absence in the present volume of coloured plates showing the malarial parasites at all stages of development, and of the trypanosomes and allied flagellates, is noticeable. The number of original diagrams illustrating life-cycles should be increased and those already included should be carefully revised There would seem little doubt that a demand for a second edition will give the author early opportunity to make these improvements

NUTRITION.

Troubles des Échanges Nutritifs By C ACHARD, Professeur de Clinique Médicale à la Faculté de Médecine de Paris, Membre de l'Académie de Médecine. Paris: Masson et Cie 1926 Two vols Pp 1220 Fr 110.

IN these handsome volumes Prof. Achard has adopted a new classification for the discussion of dietetics and all those diseases which chiefly affect nutrition. Physiology is his basis and he considers in sequence all methods by which the body can ingest gases water mineral matter, carbohydrates, fats and lipoids, and lastly nitrogenous substances. "L'esprit gaulois," says one of Meredith's characters, "sparkles with the clear crystal of common sense," and in choosing this classification Prof. Achard has not only been able to display his facts in logical sequence, but has succeeded in approaching nearer

FRACTURE OF THE ANATOMICAL NECK OF HUMERUS WITHOUT APPARENT DIRECT VIOLENCE

By F Milnes Blumer, M B , C M Edin ,
SENIOR HONORARY SURGEON, STAFFORDSHIRE GENERAL INFIRMARY

The patient, a farmer, aged 38, dislocated his right shoulder some six or seven years ago while in an epileptic fit I reduced it, and the normal function of the joint was regained On Jan 19th, 1924, I received a message to say he had again put his shoulder out On reaching the house I found him lying on his back on the floor His wife told me that, feeling a fit coming on, he promptly lay down As the fit developed he stretched his arms straight down by his side with his muscles in tense contraction The wife said she then heard a click, which told her he had again dislocated his shoulder The patient, she insisted, never fell, but had lain down quickly, as was his custom, and received no blow of any kind As the joint appeared to be dislocated, I proceeded to reduce it under chloroform, and on manipulating it I felt crepitus, and could not completely correct the deformity Examination under X rays two days afterwards revealed fracture of the anatomical neck This was confirmed when I operated a week later and removed the fragments, which were loose within the capsule There was no injury to the glenoid The wife is an observant and intelligent woman, and her statement that there was no direct violence can be accepted How, then, was the fracture caused ?

The patient has now a good range of movement at his shoulder, and is able to do all his work

THE LANCET.

LONDON: SATURDAY, JULY 3, 1926

TUBERCULOSIS AND EMPLOYMENT.

Every chronic disease has its own social and economic problems, and the unsolved problem of tuberculosis is employment In the early stage of the disease rest for body and mind is the one great desideratum, but a time soon comes when employment is essential to preserve a healthy mind in an unsound body, and many years follow in which the sustenance for an unsound body can only be derived from remunerative employment. A Committee of the Joint Tuberculosis Council undertook some 18 months ago to make a survey of the whole question of the employment of the consumptive with special reference to schemes at present in existence. This Committee, which consisted of Dr. Jane Walker (London), Dr D. P. Sutherland (Manchester), Dr. H. Vallow (Bradford), and Dr J B McDougall (Hexham), has now circulated what is in the main an agreed report dealing with all aspects of the problem—medical, social, and economic

Except in the rarest instances the worker who has broken down from tuberculosis can never safely compete again in the industrial machine Even with quiescent disease his work is apt to remain 30 or even 50 per cent less efficient than that of a healthy workman similarly trained, and the Committee was unanimous in its belief that the total number of ex-sanatorium patients who may be ultimately employed on a remunerative financial basis can only form a small fraction of those who are fit for some employment. Finance hitherto has dominated the situation, and even the modest recommendations of the Barlow Committee to provide ten village settlements of 200 to 250 families each at a cost of a million pounds has not been realised In the Committee's opinion the best method of attacking the problem is to develop occupational therapy at existing sanatoria, to make so-called training an integral part of treatment until by coöperation and efficiency it becomes possible to pay maintenance and wages for one permanent settler, then for another, and so on until a nucleus of a settlement has been formed It is in this way that successful schemes have arisen, and the Committee is able to point to examples of institutions founded de novo as training colonies and settlements with ample capital outlay where the return has been disappointing It is a necessary preliminary to ascertain what is the economic unit for any sanatorium industry. The question of markets is a business affair, and investigation into the London leather-workers' scheme for ex-patients suggests that if it could be increased so as to employ 50 men the scheme would be self supporting and the present overhead charges fully met. At some stage capital expenditure becomes inevitable unless a scheme is to be crippled by inability to extend departments of work which have been set running on sound lines; and in order to provide capital for such development the Committee recommends that sums of money from £200 to £500 should be made available after a definite scheme submitted by the medical director has been approved by the lay management responsible. Whether this money should be subscribed by voluntary contribution to a central fund or by a levy on the local authority is open to discussion, but in either case it is clear that the local authority should take its share in housing employees when that need arises. The difficulty is that in any such scheme there is singularly little margin for mistakes. No fewer than 51 different occupations have been suggested as suitable for ex-patients, and the Committee recalls a remark made by the director of the New York Tuberculosis Association, already quoted in our columns that "teaching Chinese to a negro, infusing a Latin-American with a puritanical outlook on life, or inducing statesmanship in a politician are problems equal in toughness to finding a suitable job for a tuberculous person and keeping that person in that job"

Farm work is certainly too arduous for ex-sanatorium patients, although the raising of poultry, fruit-farming, and bee-keeping are all admissible as well as the supervision of the production of the laboratory animals. Any workshop occupation chosen should be one which does not require a long period of preliminary training and which is principally repetition work resulting in mass production of an article for which there is a current demand. It is better, the Committee thinks, to specialise in a few than to have mediocre results from many employments, and for the nucleus of any department there is always needed a specialist with previous training who becomes the key-man to its output. Nor is the supply of suitable directors for such schemes likely to be abundant, for the director has to combine medical oversight with a good general knowledge of industry; no matter what facilities there may be in the way of markets or workshops or even capital, any scheme is doomed to failure without good business organisation, capable direction, and proper coöperation. But when all the requisites are present there is no limit to the possible success of such a scheme, which may grow from a small beginning to a big social movement and the Committee no doubt is right in recommending that schemes which have been admittedly successful should be encouraged to develop further by being freed from the obligation to raise capital by their own efforts Such schemes should then be copied in principle in other places.

CHOLECYSTOGRAPHY.

One of the finest examples of fruitful results proceeding from academic medical research is the evolution of tests for the function of the kidneys and liver, which was led up to by the investigation of the pharmacology of phenolphthalein compounds. Phenolphthalein occupies a curious place in physiology, for one of its compounds, the sulphone derivative, is excreted almost solely by the kidneys, whilst the halogen compounds are excreted partly by the kidney, but to a greater extent by the liver. The phenolsulphonephthalein test for renal function has been established for a number of years. When it was discovered that the chlorphenolphthalein compound was excreted very largely by the liver, an analogous test measuring the amount of the substance in the blood stream and its rate of elimination was devised for estimating the functional power of the liver cells. It having been established that the drug was excreted mainly by the liver, and the work of Rous and McMaster having demonstrated that bile is concentrated in the gall-bladder, and it having been observed that the bromo- and iodo-compounds were opaque to X rays, it occurred to E A. Graham that it might be possible to obtain a shadow of the gall-to a scientific classification than have the vast majority of his predecessors In subsections, each in its appropriate place, he discusses the disturbances attendant on the faulty elimination of the metabolic end-products, and hence his work embraces nearly all the problems of disease amenable to dietetic treatment It is clear that to be perfect his system requires an exact knowledge of the chemistry of all substances physiologically absorbed by the body, and that knowledge is not yet wholly ours Thus the diseases known collectively as " deficiency diseases " are due to an absence of food constituents still largely mysterious, and in consequence the author has included very few words concerning scurvy or beri-beri and has not attempted any discussion of less tangible forms of avitaminosis Similarly, the disturbances of health, such as chronic constipation, which are often the result merely of an ill-balanced diet, find no place in these volumes, as no upset of " nutritional exchange " can be noted in their case

In a modest preface the author points out the impossibility of including the latest advances in a book of this size, but it is so fully documented with references to the work of foreign observers that we feel that such an apology was superfluous His book will be highly appreciated by physicians in every country, and is worthy of the high traditions of French medicine

THE DIABETIC LIFE ITS CONTROL BY DIET AND INSULIN

By R D LAWRENCE, M A, M D, Chemical Pathologist and Lecturer in Chemical Pathology, King's College Hospital London · J and A Churchill 1926 Pp 167 7s 6d

WITHIN a year of the publication of this useful manual a second edition has been called for Dr Lawrence points out that while no revolutionary discoveries have been made since the book was written, yet many new facts of practical importance have been established and have been incorporated in this edition The chief changes consist in a rearrangement and further simplification of the line-ration scheme, and in the addition of some detailed examples of diet and a table for emergency use in coma We have already expressed admiration of the way in which Dr Lawrence has reduced this most complex and difficult subject to a level where doctor and patient can meet There can be no better preparation for the tedious task of training a diabetic how to control his life than a study of this little book by his medical adviser, and no surer way of acquiring the patient's cooperation than the purchase by him of another copy for his own use

---

JOURNALS

INDIAN JOURNAL OF MEDICAL RESEARCH April, 1926 —This journal contains some interesting papers M B Soparkar, as the result of extensive experiments, concludes that Indian cattle as a whole are less susceptible to tuberculous infection than are European varieties —J W Cornwall and W A. Beer describe some peculiarities of *B typhosus* in broth cultures They also suggest a method of assessing the infectivity of rabies fixed virus, and, in a further paper, discuss the effect of injection of etherised normal brain substance in connexion with the treatment of this disease —R McCarrison gives an account of an eight months' investigation into the effect of excessive lime consumption upon the thyroid gland, and his conclusions on the connexion between lime and iodine ingestion have some bearing on the ætiology of " colloid goitre "—From the Haffkine Institute, B P B Naidu, R H Malone, and C R Avari write on the potency of Haffkine's plague prophylactic *A pattoni*, a new species of anopheles found in Shantung, is described —J A Sinton publishes some investigations on subtertian crescents, and finds that the number of crescent carriers after " quinine and alkali " treatment was less than after any other form of treatment tried —H E Shortt, P J Barraud, and A. C Craighead give methods for feeding and refeeding sandflies, and in another paper describe the life-history and morphology of *Herpetomonas donovani* in the sandfly, *P argentipes* —As the outcome of a commission appointed to investigate sandfly fever in the Peshawar District, T C McCombie Young, A E Richmond, and G R Brendish publish the account of an extensive survey and give important recommendations aimed at the reduction of the sandfly

BRITISH JOURNAL OF CHILDREN'S DISEASES Vol XXIII April-June —Dr. Bernard Myers furnishes statistics concerning the height, weight, and other measurements of 1400 London school-children derived from his observations at the Children's Clinic, Cosway-street, Marylebone-road Tables are given showing the measurements of the head, chest, abdomen, intercristal diameter, height and weight for both sexes , comparisons of the height, head and chest measurements for both sexes at various ages , and comparisons of these measurements with Greenwood's figures for other English children and Baldwin's statistics for American children Myers remarks that invaluable information would be obtained if similar measurements of males and females could be made in all parts of the British Empire —In a paper on varicella encephalitis and vaccinia encephalitis Dr D W Winnicott and Dr N Gibbs have collected 12 cases of varicella encephalitis including one under their own observation The patient was a girl aged 2 years, who nine days after the onset of varicella developed symptoms of encephalitis, such as difficulty in swallowing and articulation, squint, spasticity of the limbs, and mental dullness, which lasted for about a month, after which complete recovery took place The fact that the number of days between the onset of varicella and the onset of nervous symptoms has been fairly constant in all the cases, but one is a record suggesting that there is more than a mere coincidence at work Winnicott and Gibbs have also collected 44 cases of vaccinia encephalitis , 35 of these were reported by Bastiansee in Holland, and of the others one was a case of their own of a male child aged 5 months, who six days after vaccination developed right facial paralysis, left ptosis, left internal strabismus, and convulsions Complete recovery took place within six weeks —In a paper entitled Further Observations on Acrodynia, Dr A. E Vipond summarises the cardinal signs of the disease as follows the onset appears to be a nasal catarrh, followed by a rash, which is often erythematous but may be papular or pustular The hands and feet present a bluish-red appearance, as well as the tip of the nose, ears, and eyelids The locomotor system is affected, the child being unable to walk The sensory system is also involved, there being intense pain in the arms and legs All the superficial glands are enlarged, especially those in the axilla and inguinal region Rapid loss of weight occurs The duration of the disease is from four to six months Vipond has obtained good results from the use of a vaccine prepared from an enlarged gland —Dr C I Wright reports an unusual case of herpes recurrens The patient was a girl aged 12, suffering from a moderate attack of diphtheria with an abundant eruption of herpes facialis on both cheeks, remarkable for the presence of several rounded tense unilocular bullæ, the largest of which was half an inch in diameter For the last three years the child had had recurrent attacks of herpes on one or other cheek about three times a year, but in no previous attack had the lesions been bilateral The mother, who was subject to labial herpes, stated that at the age of 4 years the child had had an attack of eczema which may really have been herpes —The abstracts from current literature are devoted to acute infectious diseases

Health Service, by those of the School Medical Service, by those of the National Health Insurance system, and by the activities of the hospitals, and, taking the whole record as it at present stands, certain broad deductions can be drawn from the facts and figures in regard to the physical condition of the English people—we can learn what has been done and judge how much remains for accomplishment Thus a steadily falling birth-rate is accompanied by a steady decline in death-rate at all ages, but with an increased expectation of life from birth upwards The infant mortality rate, though it now stands at 75 per 1000 births (one of the lowest ever recorded) is still unnecessarily high, but the burden of epidemic and infectious disease is growing lighter and with certain exceptions the figures show steady decrease both in incidence and mortality The victory of preventive medicine over certain infectious diseases has been accompanied in recent years with general improvement in sanitary environment, but both these facts call for qualification Tuberculosis, cancer, measles, and influenza are still unduly prevalent, rheumatic conditions affect a large section of the population, venereal disease, though recent activities have certainly been satisfactory in promise and performance, accounts for much sickness and mortality; while it is an open shame that the supply of houses is insufficient and frequently of discreditable quality, a position which hampers preventive medicine to an untold extent There is also far too much minor invalidity and, though the general death-rate has fallen, an undue proportion of deaths still takes place under 50 years of age Preventable morbidity and invalidity of all kinds call for the wide but intensive application of the activities of preventive medicine That is in effect the message of the Memorandum

The document is written, as might be expected, with skill in marshalling facts and in drawing succinct conclusions from them, this being done with due regard for the risks of being over positive It is sure to be widely read, as it was in its original form, by the public as well as the medical profession, and knowledge of the facts contained would form a practical adjunct to medical education Medical students in the later phases of the curriculum should be urged to read it, for it lays before them clearly and simply the fundamental principles of their future work—namely, to prevent disease

Annotations.

"Ne quid nimis"

THE PATHOLOGICAL ACTION OF LIGHT

Finsen, in a small but classic work, describes in a delightful way the response of the living to light, how birds break into song, and children into laughter with the coming of the sun Beneficent in its action in the vast majority of cases when living things are exposed to light, some pathological conditions do supervene, and these may occur either in normal people if they are given too much light or in hypersensitive individuals if they are exposed to light of an intensity enjoyed by the majority Where cause and effect are related so obviously as exposure and physiological response to sunlight it is remarkable how little is known of the mechanism of this action Could the phrases of Finsen be written in stricter physiological terms, an understanding of the pathological states induced by light would perhaps be assured As it is, information gleaned from clinician, physiologist and pathologist is grist for the mill It is doubtful whether any organ of the body could illustrate so well as the eye the different varieties of disturbances in living structures caused by light, and the recent communications of Dr W S Duke-Elder in our columns will serve not only to bring within moderate scope a host of scattered facts but also to show the complexity of the processes in front of those who essay the rôle of phototherapist While in some cases the action of the rays is attributable to an exaggerated physiological response, capable of correction by the rebalancing forces of the body, in others the upset of equilibrium in carried beyond this stage and physicochemical changes of an irreversible character, such as coagulation or precipitation, occur There appear to be two main lines of defence, apart from clothing, by which the surface of the body is protected from excessive light One is pigmentation which absorbs ultra-violet and visible light to an extraordinary degree, converting this energy into heat; the other is fluorescence, which transforms rays of short wavelength into longer ones (never shorter), in many cases thus protecting the tissues from rays which have such powerful effects upon them. Except for these processes, the body has to deal as best it may with light beating upon it The discoveries on the action of light in countering certain diseases have opened enormous fields of research, and the fact that light can endow certain foods with new and valuable properties will not be lost upon those who are seeking to explain its biological actions, for it is possible that foodstuffs within the tissues are to some extent altered by exposing the body to light. Medicine now takes stock of radiation of widely differing wave-lengths for heat, light, ultra-violet, X rays, and the gamma rays serve its various needs The pathological conditions which they have initiated in man are incomparably fewer than those they have alleviated, but the need for more investigation of the processes set going in living things by these rays is a pressing one

THE ACTION OF HISTAMINE

THE vaso-dilator action of histamine and its physiological significance is discussed by J. H. Burn and H. H Dale in the April number of the *Journal of Physiology* (vol lxi, No 2) The observations recorded were undertaken to complete those of Dale and Richards made in 1918 What may be called the histamine paradox has been the subject of much discussion In the cat, which has been the usual subject for experiment on its action histamine regularly produces, under anæsthesia, a powerful depressor effect having all the characteristics of a general vaso-dilatation; in perfused organs from the same species histamine has been found habitually to produce not vaso-dilatation, but vaso-constriction in its place. Explanations of widely different kinds have been offered for this paradox. It was found that the vessels of a cat's limb artificially perfused with blood are relaxed by histamine The tone favouring this reaction is evanescent, but can regularly be restored by a trace of adrenalin, and occasionally by pituitary extract The vessels of the limb of a monkey or dog, artificially perfused, are relaxed by histamine, and the reaction can be obtained repeatedly. The perfused arterioles of the cat are constricted, those of the dog relaxed by histamine It is suggested that the predominant incidence of the histamine dilator action on the capillaries is peculiar to the cat There is evidence that a secondary pressor effect of histamine is due to accelerated output of adrenalin; and that the depressor effect of small doses of adrenalin seen in the anæsthetised cat or dog is also a secondary effect due to liberation of a histamine-like principle The bearing of these observations on the chemical control of capillary tone is discussed. To the same issue of the journal O Inchley contributes some observations on histamine shock It is generally accepted that histamine is a direct poison to capillaries, leading to their dilatation This dilatation is associated with a fall of blood pressure and a state of collapse Capillary dilatation is the characteristic phenomenon of histamine shock as well as of shock by other substances Dale's view which is generally accepted, is that histamine acts directly on the capillaries. The author suggests another and simpler explanation to account for the effect—*namely*, that the dilatation of capillaries is passive and due to a constriction of the veins.

bladder after preliminary administration of one of these drugs. This proved to be the case, and the procedure has been developed so that it can be applied in human pathology and has received the name of cholecystography. Considering the fact that Graham's preliminary report was only published in 1924, a very considerable amount of knowledge has been collected on the subject, and the method, although not yet standardised, has become definitely established in clinical medicine. Mr. **Stanford Cade** in his Arris and Gale lecture, appearing elsewhere in this issue, has reviewed the known facts, communicated some experiments bearing on the subject, and given his experience of the method used in 100 patients. Dr. **Izod Bennett**, Dr. A. **Moncrieff**, and Dr. F. G. **Nicholas** also record this week their clinical experience in 58 cases.

There are two methods of carrying out the test, one is to give the drug intravenously and the other by mouth. Mr. **Cade** is convinced that the intravenous method is the better and regards oral administration as unreliable, whilst the other investigators, agreeing with some reports that have come from America, consider mouth administration preferable. The objections to intravenous injection are two. One is the fact that if the slightest drop of the solution escapes outside the blood-vessel into the subcutaneous tissue, extensive sloughing and inflammation occur, the other is that intravenous injection is not always without an element of danger. Even Mr. **Cade** reports two serious cases of collapse in his series and the experience of other people agrees with this, whereas after oral administration the worst that happens is that the patient may suffer from vomiting and diarrhœa. One of the essentials for the general application of a diagnostic method is that it should be without danger. There is no doubt that the intravenous method gives better shadows and is on the whole more reliable than the oral administration, so there is every incentive to make the former method as safe as the latter. It is hoped that investigations will continue in this direction. The difficulties met with after giving the drug by mouth are due to the fact that it must be protected from contact with the hydrochloric acid in the stomach, for by the action of gastric juice the chlorphenolphthalein compound is produced, a substance which is not only insoluble, but does not give a shadow with X rays. It is not easy to make a capsule which will certainly escape gastric digestion and yet be disintegrated within the intestine. Whether such solution of the capsule has taken place, however, can be seen when the subsequent skiagrams are inspected. The dose which can be administered by mouth is no greater than that by the veins, for if it is increased, vomiting is produced and the test is spoilt. If after taking the drug by either route a good shadow of the gall-bladder is obtained, it may be confidently inferred that the gall-bladder is healthy. If no shadow is seen after intravenous injection, or after oral administration, provided there is reasonable certainty that the drug has been absorbed, then the conclusion must be drawn that the wall of the gall-bladder is diseased, that it has lost its powers of concentration, or that the cystic duct is blocked so that none of the drug arrived in this viscus. Not only does the clinician take note of the presence of a shadow, he also observes the rate of diminution in size of the opaque area, which is dependent upon gall-bladder contractions.

To test the contractile power of the gall-bladder L. R. **Whittaker**[1] advises that when a good shadow with X rays is observed, food rich in cream and butter should be given to the patient. The shadow should then disappear within 2–3 hours, instead of continuing for 24. Fats have been proved to be the most powerful stimulus to contraction of the gall-bladder. Magnesium sulphate introduced into the duodenum by an Einhorn tube will also cause the shadow to shrink, but not so quickly and not to so great a degree. Gall-stones are rendered evident after the test sometimes by giving a mottled appearance to the shadow (they are transparent to the X rays and each stone causes a hiatus in the opacity), sometimes by absorbing the dye in sufficient amount to become opaque themselves. The animal experiments reported by Mr. **Cade** support the investigations of other observers, showing that none of the dye reaches the gall-bladder by the blood stream, nor is it absorbed from the wall of the gall-bladder. That is, disappearance of the shadow is due to propulsion of the dye from the gall-bladder down the cystic duct. There appear to be but few fallacies when the test is properly carried out. Even allowing for enthusiasm for a new and ingenious procedure, the results of cholecystography reported from all quarters show such a degree of reliability that the method is certain to obtain a permanent place in diagnosis.

◆

THE PRACTICE OF PREVENTIVE MEDICINE[1]

About seven years ago when public affairs in every direction were attempting to shape themselves towards the many new conditions imposed upon all society by the war, a memorandum was addressed to the Minister of Health by Sir **George Newman** entitled "An Outline of the Practice of Preventive Medicine" which formed a valuable piece of topical history. The outline was large in scope and elaborate in detail despite its title, and as it was published at a very modest price there is no doubt that many of our readers read and digested its lessons. It is certain that the great public who take an administrative as well as a theoretical interest in the progress of national health did so, for this week a new edition of the memorandum appears in response to the fact that the first edition has been out of print for some time. The form of the document has remained unchanged but a considerable amount of new matter has been added to the text, while the whole of it has been revised.

Taking as a general thesis that the purpose of the science and art of preventive medicine is to apply human knowledge to the prevention of disease, the author, after a brief disquisition on the modern developments of medicine, especially in practical application, analyses the nature of disease, showing that the body must be judged by its heredity, nurture, potentialities for nutrition, and its habits when estimating its resistance to injury—or infection, resistance to infection introducing the principles of epidemiology. These are laid down in a few clear lines, in which the secular trend, the epidemic constitution cycle, the seasonal cycle, the climatic and immunisation factors, and the biological change of state of the virus are considered, indicating the all-round nature of the document and the determination of its author to explain what he intends to teach. In face of the actual problems we have indicated the various avenues of approach to their comprehension. The main directions in which the practice of preventive medicine has to be conducted for the public good are illustrated by the results generally of the Public way. Sulphosalicylic acid precipitates albumin In these ureas there are sulpho-acid groups which act on the albumins of the parasites (perhaps on the protamine) forming salts that are only slightly soluble Thus the chromatin from the milt of herrings is a neutral salt, clupein nucleinate. and the clupein base combines with acid dyes to form salts insoluble in water. In the same way. the bases in the cell contents of the parasites (trypanosomes and the like) combine with the sulpho-groups of Bayer ' 205 ' to form barely soluble salts, the parasitic chromatin being therewith hampered. as if filled up with bird-lime or with glue, made physiologically less active, and the cell is to some extent thus withdrawn from metabolism. Many substances have been examined, and those that gave the best antiparasitic results had only the sulpho-groups in common, so it was this group that was thought to be the effective part Ureas with either benzol or naphthalin groups may be effective. but they must have large molecules if their action is to be lasting and they must have a certain number of sulpho-groups able to combine with basic substances in the cells of the parasites to form salts only slightly soluble in water Little is known of the bases that exist in albumins. The chemist cannot say in advance whether the salts will be soluble or no only actual experiment can decide that. The acid part of the substituted urea combines with the basic part of the chromatin of the parasite. metabolism is slowed. cell division is hindered, and reproduction is delayed or ended for the time. In this series of antitrypanosome drugs although there is no toxophore group, like the poison on the arrow, kept applied by the haptophore barb yet the haptophore sulpho-group attaches itself to the chromatin, and so lowers the vitality of the parasite that it dies tired out, like a whale worn out in dragging the ship after him by the rope, though the harpoon was not poisoned The subsequent distribution of the drug in the host or patient is important. It may circulate in the serum and be thence taken up by the parasite at once, and at times this action takes place very quickly · in 15 or 30 minutes the parasites may be so much altered that though their number is unchanged. the blood is no longer infectious If the drug remains in the serum it is probably effective for a shorter time than if it is absorbed and stored by the cells of the body—on the analogy of Congo red which is at once taken up from the blood by waxy or amyloid substance, so that none remains in the serum after a very short time. Variation in storage explains why the effective dose against the same parasite differs in different animals. If the drug is stored, it is gradually released and eliminated whereby the parasite has a prolonged exposure to the drug, though at a lower concentration When the drug has been nearly eliminated its " pressure " falls too low. and the parasite, if not already destroyed, begins again to increase and the patient suffers a relapse, unless given a new dose. Hence the reason for a course of injections The weakened parasite may succumb to the protective chemistry of the host (i.e the antibodies formed), but if the host has no protective power and cannot form antibodies, antimony may be given. Races of parasites may be grown immune to particular ureas but still susceptible to others perhaps even to others closely allied The constitution of the parasite has been so changed that it has learned slightly to alter the bases in its albumins so they shall not form any but soluble salts with the acids in the drug Picric acid has a very similar action but nitrates are less useful than sulpho-salts for the molecule of soluble nitrates is too simple while the nitrates of sufficient molecular weight are too insoluble to be available for injection On the other hand the soda salts of the sulpho-acids are easy to work with Dr Roehl concluded his review of the action of " germanin with an expression of gratitude to the chemists who. led by Dr. Heymann had worked with him Only by effective combination of chemist and chemotherapeutist, he said, can results be won

SLEEPING SICKNESS IN TANGANYIKA TERRITORY.

An epidemiological survey of human trypanosomiasis is at present being undertaken by an international League of Nations Commission in Central Africa. Prof F K Kleine is engaged in Tanganyika Territory on this work The extreme variations in pathogenicity of the human trypanosomes, as well as the diversity in the clinical aspects of the disease in widely separated districts are among the complex problems being studied. The outbreak in Mwanza on the south-eastern shore of Lake Victoria in 1922 was originally investigated by H. L Duke [1] and C. F M. Swynnerton.[2] Several interesting and novel facts were elicited during the course of this epidemic which proved to be one of exceptional severity. It was found, contrary to expectations, that the trypanosome belonged to the *rhodesiense* type and was transmitted in a direct manner from one infected individual to another by a new species of tsetse-fly which became known as *Glossina swynnertoni*. It could not be definitely ascertained whether or not the particular outbreak was attributable to the fact that in the absence of big game, which had entirely deserted the district, the tsetse, deprived of this service of food-supply, had been entirely dependent on human blood The novel views of Duke and Swynnerton have been opposed by J. B. Davey [3] from his own personal experiences in this territory. A recent report to the Secretary of State for the Colonies concerning sleeping sickness in Tanganyika Territory would seem to indicate that the *rhodesiense* infection is more widely spread than had been supposed. Prior to 1914 this infection had not been recorded further north than the shores of Lake Nyasa Now we understand that Rhodesian sleeping sickness exists in (*a*) the Mwanza area, where the original outbreak was discovered in 1922; (*b*) near Ikoma, situated about 50 miles north-east of the area mentioned above (there is considerable inter-communication between the natives of these two areas and it is possible that at least some of the cases detected in the Ikoma district were infected in the Mwanza): (*c*) in the Liwale sub-district of Kilwa—this appears to be a localised outbreak of low virulence: (*d*) in the southern portion of the Tabora district and northern part of Ufipa. This is the most extensive area found to be infected, more than 10,000 square miles of country being involved Approximately 300 cases have been reported with 90 deaths The type of disease is similar to that described in Nyasaland and by Kinghorn in Northern Rhodesia cases being found in villages widely separated. and as a general rule only a very small portion of the inhabitants are infected. Rarely the disease becomes epidemic in a localised community, and when this is so it appears probable that some concomitant cause is present, such as marked shortage of food. This not only results in lowered vitality but also in increased contact with the fly due to more frequent visits to the forest for the purpose of hunting and in search of food The methods adopted to prevent the spread of the disease have in the main been confined to the treatment of infected cases and the concentration of the population in fly-free clearings. Treatment has been principally by ' Bayer 205 ' and by tryparsamide. The former has proved very effective in early cases when given in adequate dosage while tryparsamide gives better results in cases in which the nervous system is involved. Cases of sleeping sickness due to infection by *Glossina palpalis* continue to occur in the neighbourhood of Kigoma 14 cases being reported

In a circulation through intact arteries, capillaries, and veins, where a variable resistance may be imposed in any one of the three, it is difficult to draw conclusions as to which is affected in altered circulatory conditions Experiments were devised to examine each of these factors separately On isolated organs of cats and rabbits—e g , intestine, liver, muscle of a limb—experiments were made with perfusion of arteries and capillaries without veins, and perfusion of veins and capillaries without arteries In an excised loop of small intestine of the cat perfusion with oxygenated Ringer with the addition of histamine phosphate was made through arteries or veins without capillaries Ring preparations of the mesenteric artery and vein of the pig were studied when immersed in Ringer's fluid, to which different concentrations of histamine were added and the effects recorded The results suggested that vascular constriction under histamine is mainly venous Experimental occlusion of veins—inferior vena cava above the entrance of the renal veins, and the portal vein—was made in anæsthetised animals Large veins were painted with a strong solution of histamine in an anæsthetised animal and the effects—local and general—studied , and lastly, the effects of intravenous injection of large doses of histamine were examined The author discusses his results, and concludes that histamine in low concentrations constricts the veins, leaving the arteries unaffected, such constriction leading to passive dilatation of capillaries Long-continued occlusion of great veins leads to permanent relaxation of capillaries The author concludes that histamine shock is best explained by venous constriction

THE ÆTIOLOGY OF ECZEMA

THE perplexing problem of the ætiology of eczema is discussed by Dr F F Coombes in an authoritative essay forming part of a symposium on dermatology recently published in America [1] He stresses the fact that during the last 50 years the frequency of this diagnosis has been reduced from about 60 to 20 per cent of all cases of skin disease, and explains the reduction as due to (1) the recognition, both microscopic and cultural, of a large class of bacterial and mycotic parasitic infections , and (2) the elimination from the scrap-heap of eczema of those cases of dermatitis which are dependent on an external cause of irritation and do not proceed to the formation of vesicles As examples of the first class are instanced seborrhoeic dermatitis, infectious eczematoid dermatitis, due to the *Staphylococcus aureus* and *albus*, and cured by the local application of mild antiseptic remedies, and a very large and increasing group in which a member of the ringworm family is the demonstrable cause In the second class are placed a heterogeneous variety of dermatoses which include neurodermatitis and the huge class of trade eczemas The effects of scabies, pediculosis, hair-dyes, and other external irritants are also in this category The author, in common with most members of the modern school, is driven to the conviction that external irritation alone is not a sufficient cause for eczema, for otherwise all persons working in a noxious atmosphere would be equally liable Some idiosyncrasy, with the subsequent development of local sensitivity, has to be assumed for all the cases of eczema which arise after any kind of external irritant has been applied, or without such an obvious and immediate cause—i e , de novo Dr Coombes quotes an interesting experiment by H Jaeger 140 patients with normal skins, and 77 with eczematous lesions of various types, were all submitted to the same routine tests with external irritants Only 4 per cent of the normal persons showed any reaction, while 55 per cent of the eczematous developed new lesions on the irritated area indistinguishable from acute vesicular eczema Jaeger concluded that this susceptibility was due to a tissue idiosyncrasy and not to a humoral defect or internal dysfunction The attractive though rather fanciful theory of Ehrman, that eczema can be caused through the invasion of the circulation by way of the gastro-intestinal tract of relatively large protein molecules, which irritate the skin papillæ and cause exudation, has a certain number of supporters Such a mechanism is more likely in urticaria Hypoacidity (Uhrbach) of the gastric secretion may be a factor in some cases, but there are many with which hyperacidity is associated The correction of the gastric disorder only rarely results in a cure of the eczema That eczema is due to some disturbance of the metabolic ratio—i e , an excessive intake of carbohydrates, fats, or protein—is a theory which is at present popular, particularly as regards the eczema of infants Against this it is observed that while skin affections of more than one kind may occur in diabetics, there are many patients with a high blood-sugar who have no cutaneous lesions The same can be said of those with excessive uric acid content of the blood This is just as likely to be a result as a cause of eczema It is possible, however, that variations in the chemistry of the blood may have a sensitising effect on the skin and so favour the development of the disease

The theory of food allergy appears to attract Dr Coombes more than any other He instances egg protein as a cause in infants particularly Wheat can act in the same way, and there may be a combination of two or more proteins noxious to one individual In the majority of food-allergy eczemas, asthma is associated or may alternate with the eruption Cutaneous tests are not always successful in determining the actual protein and the manner in which they act is undetermined One theory is that the vagotonic nerves are irritated, " producing areas of capillary dilatation with pruritus," which react to scratching by the production of vesicles (eczema) But most of such protein cases are dry and papular, and do not vesiculate , many of them are classed as neurodermatitis, and therefore do not really fall into the same category The part played by food protein in the causation of eczema has naturally led to the assumption that bacterial proteins may act in the same way The author states that he has never seen a positive reaction to a bacterial protein which, given later as a vaccine, brought about a cure of the eczema The influence of the endocrine glands is considered in a short paragraph, and dismissed with the observation that they constitute only one factor in maintaining a balance of nerve control (equilibrium of the vagotonic and sympatheticotonic nervous systems), and can therefore be regarded only as a contributory cause of the disease

THE MODERN GERMAN VIEW OF BAYER "205"

Dr W Roehl, one of Ehrlich's early co-workers in chemotherapy, recently reported[1] to the German Tropical Medical Fellowship at its Hamburg Congress, on the action of Bayer " 205," now known in Germany as " germanin " Dr Roehl's work has been done in the chemotherapeutical laboratory of the Elberfeld Dye Factory Bayer " 205 " belongs, he says, to the large group of complicated urea-substitution products of the aromatic group, having in its molecule no metals or metalloids exerting chemotherapeutic action, no mercury, bismuth, arsenic, nor antimony Its molecular constitution was published [2] in 1919 How, asks Dr Roehl, does such a substance act on blood parasites ? It has none of Ehrlich's toxophore groups, nor such haptophores like OH or NH_2, and yet everyone is in agreement that it does not act primarily on the patient, encouraging antibody formation, but directly on the parasites, for very slight changes made in the molecule at once varied the effects on the different individual parasites. Dr Roehl answers his own question in the following costly physically defective schools will be very greatly reduced. Among the schemes which are described in this report that dealing with Bath, Wilts and Somerset is noteworthy. To serve as the central hospital for this an entirely new hospital was built near Bath, remarkable for its low cost considering the durable nature of its construction, which is due largely to the simplicity of its design and materials. Excellent work has been done here and at the clinics in all kinds of orthopædic cases and especially in the treatment and correction of faulty posture. In Birmingham an amalgamation of the Royal Orthopædic and Spinal Hospital and the Birmingham Cripples' Union has made an efficient organisation of the care of cripples possible. The area for which it will take responsibility is a very populous one including besides the city the huge industrial area known as the Black Country. In this report due credit is given to the Invalid Children's Aid Association, which has done and is doing so much good work on the care of cripples after their discharge from hospital and while they are attending as out-patients. Similar good work is done by the Central Council for Infant and Child Welfare at other places and the relations between these societies and the Central Committee for the Care of Cripples are close and cordial and likely to become even closer, thus ensuring coördination and avoiding overlapping of activities.

VENTILATION IN FACTORIES

VENTILATION up to recent years has been a Shibboleth rather than a science, a term which conveyed more comfort than meaning to those that used it. It was bound up with the replacement of vitiated air by fresh air, though what constituted vitiated air was not specified with any precision. Little wonder that engineers striving to meet indefinite requirements only succeeded at times by happy chance, and more often lamentably failed. New conceptions have now been introduced which, while not disregarding the chemical aspect of the subject, take into account also the cooling power which is largely a function of movement. It is indeed now accepted that neither the chemical purity of the air nor the temperature (whether dry or wet bulb) is an accurate index of the physiological effect of the environment, but that in addition to both of these the rate of movement of the air must also be estimated. The matter has been extensively explored in this country for the Medical Research Council by Dr. Leonard Hill and his colleagues, and in America by C. K. Drinker, C. P. Yaglou and others. The knowledge already acquired has been applied by the Industrial Fatigue Research Board with considerable success to factory premises, particularly where some abnormal condition of heat or humidity prevailed, as in steel smelting or humid weaving. The most recent report[1] on fan ventilation in a humid weaving shed describes an experiment made for the Departmental Committee on Humidity in Cotton Weaving which was appointed in November, 1924, by the Home Secretary.

The effect of suitably arranged electric fans on atmospheric conditions in the shed, on warps and on output, and the effect of humidity and temperature on warp breakages and on output were studied, and special efforts were made to ascertain the opinions of the weavers on the innovation. The general conclusions reached were as follows: (1) The cooling power of the air and bodily comfort of the operatives were considerably increased by the particular arrangement of fans adopted. (2) Without fans, the cooling power of the air never reached the minimum standard considered necessary for workers engaged in sedentary occupations. (3) By running the fans at different speeds according to the atmospheric conditions in the shed it was possible to maintain a fairly uniform rate of cooling until a temperature approaching 85° F. was reached. Above this temperature more powerful fans would be necessary to preserve the same effect. (4) Equally satisfactory results were obtained by the use of other smaller fans which were effective over the area covered by four looms under the control of one weaver. (5) The increased air movement produced by the fans had no significant effect upon the number of warp breakages on the looms in their immediate vicinity. (6) There were indications that the output on the looms affected by the fans was somewhat higher on the days when the fans were running. (7) The number of warp breakages decreased as the relative humidity increased. (8) The number of warp breakages decreased as the temperature increased. (9) The highest output was obtained when the temperature was from 72.5° to 75° F. and the relative humidity 75 to 80 per cent. With higher temperatures and humidities the output decreased.

Investigations have also been extended to the more normal conditions of ventilation and heating, such as prevail in shoe or engineering factories, or in schools. The results obtained by Dr. H. M. Vernon and Mr. T. Bedford have been embodied in another report.[2] Generally speaking, the authors have not found that expensive artificial ventilating systems installed even in new factories, produce the desired results, which may be summarised as keeping the air in such motion as to give a sensation of freshness and keeping the feet warm and the head cool. On the whole, natural systems of ventilation are regarded as preferable, being more pleasant and more healthy. The report contains a number of tables and diagrams embodying the details of a large body of observations carefully made. Natural ventilation by windows, particularly in summer, is pronounced to be good. Exhaust ventilation may be of some advantage, especially in winter, but it should not be at the floor level. The plenum system was found to compare disadvantageously with other systems. Heating is best effected through surfaces warmed to a fairly low temperature, and placed either in the floor or as near as possible to the floor. An ideal method would be to place hot-water pipes or radiators under the floor so as to heat the whole of the floor material, as in the old Roman hypocaust. Thus we find the researches of modern science justifying the old-time usage—the open window and the heated floor—in contrast to the more expensive, complicated, but misdirected efforts of recent days. Evidence is quoted confirming the fact that even moderate differences in atmospheric conditions exerting a definite influence on well-being as measured by lost time. The more does ventilation diverge from the optimum standards, whether on the side of excess or of deficiency, the more does lost time for sickness increase.

POLONIUM AND THE TREATMENT OF SYPHILIS

QUITE early in her classical investigations into the radio-active substances present in pitchblende Madame Curie isolated a very active element which was named polonium in honour of her native country. This substance is now also known as Radium F and is one of the final disintegration products in the uranium-radium series, closely resembling bismuth. It is this close resemblance to bismuth which has led C. Levaditi and others to experiment with polonium in the treatment of syphilis. They have recently reported[3] the effects of intravenous injections of polonium in the case of rabbits with chancres produced by inoculation with the syphilitic virus. Since polonium is intensely radio-active its presence and its concentration in any organ of the body can be determined by radiological methods; as a further experiment spirochætes were taken from the chancres after the injection of polonium and examined for motility. A solution containing during the year. A medical officer is now stationed at Kasanga at the southern end of the lake and it will be possible in the future to make a more detailed examination of the inhabitants of the lake shore. While there seems little danger of a widespread epidemic of sleeping sickness occurring in the territory, there is no doubt that the large areas infested with *G. morsitans* are a constant menace. The problem is a large one, and sanction has been obtained to create a distinct branch of the medical department to deal exclusively with trypanosomiasis. This will be under the control of a medical officer with considerable experience of sleeping sickness and will be staffed by officers who show special aptitude for this work.

THE DIRECTOR-GENERAL, A.M.S.

Major-General Sir Matthew H. G. Fell, K.C.B., C.M.G., has been appointed Director-General, Army Medical Services, in succession to Sir William Leishman. Major-General Fell served in France and Mesopotamia during the war with great distinction and success, and was eight times mentioned in despatches. In 1918 he was lent to the Air Ministry and acted as Director, Medical Services, R.A.F., till 1921. Subsequently he became Inspector, Medical Services of the Army (1921–22), and Deputy Director, Medical Services (1922–26), serving in Turkey, in the Northern Command, and in Egypt. He returned from Egypt to take up the appointment of Deputy Director-General, Army Medical Services, on June 1st, the day before Sir William Leishman died. He enters on his responsible duties at the moment of great reforms.

SPIRITUALISM.[1]

A CONSECUTIVE history of modern spiritualism on general lines was required, and Sir Arthur Conan Doyle tells the story "with such obvious sincerity," investing it "with such vibrant interest, that its appeal is by no means confined to professing spiritualists." The quotation is from the publishers' statement on the cover, and we are happy to take it over. The work has grown from small disconnected chapters into a narrative, we learn, and it appears to deal in a way with the whole spiritualist movement, its serious approach being accentuated by a statement in the preface that this movement "is regarded by many as the most important in the history of the world since the Christ episode." In the first volume we have the story of, among others, Swedenborg, Edward Irving and the Shakers, Andrew Jackson Davis, Home, the Davenport and Eddy brothers, while there is the fullest account of the association with the phenomena of spiritualism entered upon by Sir William Crookes. The well-known story of mysterious rappings at Hydesville is also told, and their inexplicable nature is dwelt upon in an appendix as a communication from Horace Greeley, the great publicist, who founded the *New York Times*. In the second volume we have the story of Eusapia Palladino, an illiterate Neapolitan, whose manifestations were decided by the Society for Psychical Research to be fraudulent, and it is certainly a proof of the perfect honesty with which Sir Arthur Conan Doyle deals with the subject that he should have told the record of this lady in such detail, her adventures in spiritualism are usually quoted as an argument for the credulity of spiritualists. A chapter concerned with the activities of the Society for Psychical Research is interesting, for it is known that the outcome of the work of the Society is confusing. Sir Arthur Conan Doyle finds the record of the Society to be a strongly blended one of usefulness and obstruction, furnishing us with reasons for the belief that its investigations have been conducted without bias. In other sections of this volume we come across the well-known Mrs. Piper, the material manifestations of "ectoplasm," the results of "spirit photography," and the poignant association of spiritualism with the war. The volume closes with sections upon the religious aspect of spiritualism and the after-life as seen by spiritualists. These and many other aspects of spiritualism do not enter into the province of medicine, and we must here regard the work as one written by a medical man and sent for review to a medical journal. Inside this reference it is right to recommend our readers to ascertain for themselves from Sir Arthur Conan Doyle's pages what a devoted worker along spiritualistic lines who has the advantages given by a scientific training, can say for a movement which, while it has none of the awful significance alluded to in the preface, is stirring deeply the imaginations and possibly influencing the lives of a large section of the public. The volume is well illustrated, largely with portraits of prominent supporters of spiritualistic theories and work.

THE CARE OF CRIPPLES.

THE Central Committee for the Care of Cripples seeks to fulfil very similar functions to those which the Charity Organisation Society exercises in a more general sphere. The investigation of the causes of crippling and their elimination, and the coordination of all the agencies which seek to provide treatment and training are among the objects which it pursues. The second biennial report for the years 1924 and 1925 is able to record very great progress since the publication of the first. Comprehensive schemes, generally on a county basis, have been adopted in many parts of the country and the blanks on the orthopædic map of England seem in a fair way to be filled up, but a great deal of constructive work is still to be done. The foreword of the report concludes by pointing out that the test of a successful scheme will be when those who work it see that they can get help in their task from all sources. Besides the treatment of physical disability, the training and employment of the cured cripple offers a problem for solution. In London such education is more or less provided for, but elsewhere it is extremely difficult to find means of technical training for a cripple over school age. Even after the cripple has received his training he may be handicapped by some residual disability and be unable to compete on an equality with his normal work-mates. A scheme intended to deal with this problem was started in Oxfordshire, and as a result the Ministry of Labour has approved the establishment of a special committee in each area, on which juvenile employment exchanges, employers, and trade-unions should be represented, as well as members of the staffs of hospitals and clinics who know the capacity and limitations of the cripple. Such committees are already at work in the Oxfordshire area and in Hertfordshire. In the April number of the *Cripples' Journal* will be found the concluding portion of a brief autobiography of a cripple, a moving but true story which shows the terrible trials which some cripples have to undergo. The particular case was no doubt an exceptionally severe one and not typical of the great majority of cured cripples but it nevertheless brings home to the reader a sense of the difficulties inherent in the search for remunerative employment for cripples. This number of the journal contains much that is interesting concerning surgical tuberculosis, occupational therapy, and other subjects. It has for the last two years been published quarterly at Oswestry, but henceforth its office will be in London, and with the July number it becomes the property of the Central Committee for the Care of Cripples. We wish it success in its new circumstances. A systematic and widespread organisation for the care of cripples needs money, and this is a peculiarly bad time to get it from an impoverished country and an overburdened Treasury, but it has been shown that the crippled child, if properly treated and looked after, is in most cases fit to attend an ordinary school, and thus the expenditure upon the with half a grain of tartarated antimony, or 4 to 6 drachms of the vinum ipecacuanhæ may be given. In the persistent cases, also, a dose of chloral (15 to 20 gr) may give relief For the preventive treatment between the attacks, any exciting cause should be discovered and treated, particularly pharyngitis, chronic laryngitis. over-indulgence in tobacco or alcohol and indigestion · in some patients a spasm is readily induced by drinking cold fluids. which must then, of course, be forbidden. A general tonic and hygienic régime is indicated and a change of air and scene is often of value. Little can be expected from drugs but a course of a mixture containing sodium bromide gr x.. with tincture of nux vomica ♏vi , three times a day may be useful Hysterical cases usually show an obstinate tendency to recurrence; and in those due to aortic aneurysm or mediastinal tumours, the treatment is of course. purely symptomatic. The laryngeal crises of tabes are usually quickly relieved by inhalation of amyl nitrite

---

[1] The History of Spiritualism. By Arthur Conan Doyle, M.D., LL.D. In two volumes. London, Toronto, and New York: Cassell and Co. 1926. Vol. I., pp. 342; Vol. II., pp. 342. 42s.

Glottic Spasm in Children

Because of their high reflex excitability. children are much more liable than adults to spasm of the glottis as a result of local or reflex irritation and by reason of the relatively small size of the laryngeal lumen, a degree of narrowing which in the adult would cause little trouble produces in a child severe and urgent dyspnœa. Spasm plays an important part in most forms of laryngeal disease in children, and therefore their dyspnœa is characterised by exacerbations, which usually occur at night, and by intermissions. either complete or partial according as the spasm is the sole or the partial cause.

Laryngitis Stridula —In some children spasm readily occurs in the course of a catarrhal laryngitis and produces the condition called *laryngitis stridula* or "false croup." The child has a cold, with slight pyrexia and hoarseness. but during the evening or night respiration becomes embarrassed and inspiratory stridor ensues with recession of the ribs and epigastrium and. in some cases, an alarming degree of asphyxia. The symptoms tend to subside towards morning, but may be repeated during the next few nights though nearly always with diminishing severity. The child must be put to bed in a warm but well-ventilated room At the onset one or two grains of calomel should be given, and repeated in three hours until the bowels have acted freely. and the drug may usefully be continued in half-grain doses three times a day; one minim each of tincture of aconite and vinum antimoniale may be given every two or three hours If any dyspnœa appears, an emetic is the best means of allaying the spasm and of clearing the bronchial tubes of secretion; ipecacuanha is by far the best drug for this purpose and may be given to a child of 2 years of age in doses of 1 drachm of the wine, or 5 gr of the powdered root, every half hour until vomiting occurs Whitla recommends 10 minims each of vinum antimoniale, vinum ipecacuanhæ, and syrupus scillæ in a teaspoonful of water every 15 minutes until vomiting is produced When the child has recovered any predisposing source of irritation must be sought out and treated. In a large number of cases this is in the pharynx; in fact. children subject to laryngeal spasm nearly always have adenoids and enlarged tonsils, which must be removed; gastro-intestinal disturbances should receive treatment and cod-liver oil malt and preparations of iron are helpful during convalescence

Laryngismus Stridulus.—There is another form of "false croup" in which there is no inflammation or other disease of the larynx, this is called *laryngismus stridulus*, and occurs in feeble, unhealthy children, usually between the ages of 6 months and 2 years, often in association with rickets, and nearly always with adenoids or enlarged tonsils. The attack is shorter and sharper than that of laryngitis stridula and like it often occurs at night In a typical severe attack the child awakes suddenly struggling for breath with inspiratory stridor, retraction of the lower ribs, and cyanosis; at the height of the attack air may completely fail to enter, and there may be convulsions carpo-pedal contractions. and evacuation of urine: the end comes with a long crowing inspiration, and the child then generally goes to sleep. Death during an attack is very rare. but a feeble child may become worn out and die from pulmonary collapse. Shorter and milder forms are more common and are called by nurses "passion-fits" Laryngismus has usually been ascribed to spasm of the glottis but a simpler explanation may hold good for some cases. a child with nasal obstruction from adenoids becomes partially asphyxiated while asleep and. under the deep gasping inspiration which follows, the soft flaccid laryngeal walls are sucked in and close the lumen In the treatment of the attack it must be remembered that it lasts but a few minutes, and that there is only time for rapidly acting measures The quickest and most effective method is to pull the epiglottis forward with the forefinger passed to the base of the tongue. a manœuvre which can easily be taught to mother or nurse; other measures are to stimulate the conjunctiva by touching it with the finger. the lips by brisk rubbing with a towel. the face by cold sponging, or the nasal mucosa by tickling with a feather, or by smelling salts or inhalation of nitrite of amyl. There is no time for the hot bath sometimes recommended, nor for tracheotomy or intubation, which would in any case hardly ever be necessary. Of preventive treatment, the most important is the removal of adenoids and enlarged tonsils; overloading the stomach must be carefully avoided. and the bowels should be regulated. Most of these children being "delicate" are clothed too heavily and kept in overheated rooms As much time as possible should be spent in the open air, and a reasonable amount of exercise should be taken. A change of air, especially to a high, dry locality, is of value; Moritz Schmidt found benefit in moving a child to the top floor of the house. Of drugs cod-liver oil and iron tonics are the most helpful: sedatives such as bromides and chloral. are depressing and should be avoided; Eustace Smith recommended liquid extract of grindelia, which may be given in milk or sweetened water in doses of 10 to 30 minims four times a day. The affection. in short is most successfully treated if regarded as the result of debility rather than of excessive nervous excitability.

HAROLD BARWELL, M.B Lond.. F.R.C S. Eng ,
Surgeon for Diseases of the Throat and Ear,
St George's Hospital.

TUNBRIDGE WELLS GENERAL HOSPITAL.—In 1928 the hospital will celebrate its centenary, but it is unlikely that the existing building in Grosvenor-road will still be in use at that time. The building has outgrown its requirements and rather than face an expenditure of £30,000 on alterations the governors on June 21st unanimously decided to erect a new hospital on an eight-acre site at Great Culverden, Mount Ephraim. The total cost has been put at £80,000 but it is proposed to sell the freehold of the Grosvenor-road site, and certain other funds are available. Probably about £35,000 will have to be raised by public appeal. The new scheme includes provision for 150 beds a nurses' home, and an administrative block, and also for the carrying on in the same building the work of the Eye and Ear Hospital. It is likely to receive hearty support.

NEW TORBAY HOSPITAL.—A year ago Mrs Ella M. Rowcroft, of Pilmuir, Torquay. gave a sum of £100 000 to purchase a site for the new Torbay Hospital , this brought her gifts to the Torquay Hospital Committee to a total of £123 000 On June 26th in the presence of about 3000 people, Mrs Rowcroft laid the foundation-stone of the new building at Hengrave, Torquay. The site chosen is about a mile from the present hospital in rural surroundings and particular attention is to be paid to the provision of good accommodation for the medical and nursing staff The present hospital has long been entirely unsuitable, both from the point of view of the needs of Torquay and the comfort of the staff It is expected that the new hospital will be completed in about 18 months, and the committee in charge is now engaged in raising an endowment fund of £40,000

200 electrostatic units of polonium was injected intravenously into three rabbits, all with chancres on the scrotum, and they were killed on the third, fifth, and tenth days respectively after injection. The various organs of the body were then examined The shadows cast by each organ on photographic plates was noted as a sign of the amount of polonium it contained, histological investigations were also made. The results showed that polonium injected intravenously could be found in a relatively important proportion at the site of a primary syphilitic lesion By comparing the radiographic and histological findings it was ascertained that the necrosed central portion of the chancre contained no polonium, which accumulated particularly in the zone of reaction around the necrotic area In each case polonium was found in greater concentration in the principal organs of elimination, such as the kidneys, liver, and lungs On the other hand, the amount of polonium at the site of the chancre became progressively greater in the days following its injection while the amount in the liver and lungs rapidly diminished Despite this apparent concentration at the site of the primary syphilitic lesion, however, there appeared to be no appreciable action on the spirochætes removed for examination The dose of polonium employed was very small on account of its extreme "physical" toxicity, and despite the negative results obtained with regard to the destruction of spirochætes the experiments here described do appear to indicate that there is probably a definite concentration of heavy metals at the site of a syphilitic lesion Such an indication is important in view of the resemblance between polonium and bismuth, for bismuth has now become an important addition to the list of drugs used in the treatment of syphilis

BRITISH HOSPITALS ASSOCIATION

SEVERAL important subjects came up for discussion at the Sixteenth Annual Meeting and Conference of the British Hospitals Association held at Portsmouth on June 24th and 25th, under the presidency of Sir Harold Pink, chairman of council The proceedings opened with a paper by Mr Herbert L Eason (superintendent of Guy's Hospital, London) describing the movement to provide pensions for hospital servants and giving a critical summary of the scheme approved by the King Edward's Hospital Fund for London, which has now been laid before the hospitals by the Fund, and may well be adopted widely. Mr Eason's explanation of the scheme elicited warm approval Great interest was also felt in Sir John Paget's plea for an amendment of the law to allow hospitals to recover the costs of treating accident cases for which compensation is paid It is obvious that the present situation is anomalous If a person is injured owing to the negligence of a motor driver and is taken home to be treated, he can recover damages covering the expenses of private nursing and private medical attendance; but if he is admitted to a public hospital he cannot afterwards recover a penny to meet the cost of maintenance there, because the hospital is a charitable institution and could not sue him if he did not pay Sir John Paget considers it wrong that the hospitals, which cannot refuse to admit a serious accident case, should be expected to give prolonged treatment of this kind without having their expenses covered It may be argued, he said, that it is the business of a charitable institution to be charitable, and this he admits in so far as it applies to the actual victim of the accident. The present state of things, however, violates the old maxim of Roman law that he who gains the benefit should bear the burden; for it is the negligent motorist who gains by the efficiency of the hospital's service, because the compensation he will have to pay varies as the amount of permanent injury On the second day of the Conference Dr S C Dyke read an interesting paper on the Pathological Service of the General Hospital, in which he laid stress on the fact that "pathology is not ancillary to medicine, it *is* medicine, and a hospital without a pathological service is incapable of proper function" He discussed the place of the hospital laboratory in the scheme of panel practice and laid down some important principles of administration We hope to give the subject fuller consideration shortly

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CLXXIX —SPASM OF THE GLOTTIS IN ADULTS AND CHILDREN

THE effect of spasm of the laryngeal muscles is to produce closure of the glottis, for, though the abductor muscles probably participate in the contraction, they are overcome by the more powerful adductors In addition to the adduction of the vocal cords, there is closure of the ventricular bands and, in any strong spasm, contraction of the sphincter of the upper aperture of the larynx The spasm is most frequently the reflex result of irritation in or near the larynx It will, of course, occur in anyone who inhales a foreign body or an irritating vapour, but it also occurs occasionally with less powerful stimuli, as in a simple laryngitis or pharyngitis, and here we must invoke an excessive reflex excitability as a further ætiological factor Secondly, any lesion which causes irritation of the recurrent laryngeal nerve in the neck or in the mediastinum may produce spasm, among these are aneurysm, neoplasms, and diseased glands in the neck or thorax Thirdly, the cause may be a central nerve lesion, the laryngeal crises of tabes dorsalis, these resemble any other attack of laryngeal spasm, and may appear very early in the disease, before other symptoms have occurred to suggest the diagnosis Fourthly, spasm may be of purely functional or hysterical origin, and may or may not be associated with globus hystericus, anæsthesia of the fauces, or other paræsthesiæ

A typical attack of glottic spasm begins with a tickling sensation in the throat, followed by a fit of coughing, the glottis then closes, inspirations are taken with difficulty and accompanied by loud stridor, but expiration is unimpeded In the severest cases the glottis is completely closed at the height of the attack, the signs of asphyxia are present, and there may be, though this is rare, complete loss of consciousness The spasm in this severe form lasts but a few minutes, in many cases it is less complete, but persists for several hours

Though very alarming to the patient, glottic spasm is not dangerous, except when due to serious disease, such as locomotor ataxy or thoracic aneurysm, it is only in such cases that tracheotomy is ever required The attack is generally too short and sharp to leave much time for direct treatment The fears of the patient must be allayed as far as possible, and he should be told to try to take quiet, shallow respirations through the nose The inhalation of nitrite of amyl frequently gives relief, and the patient subject to these attacks should be advised to carry a 5-minim glass capsule of this drug for immediate use when required The spasm always disappears under chloroform, which may be administered, when time permits, by the medical attendant; it need not be given to the extent of inducing anæsthesia. StClair Thomson recommends, for inhalation, a breakable glass capsule containing chloroform ♏x, menthol gr ⅓, and ethyl iodide ♏v A hot sponge applied over the larynx is a useful minor measure In the more persistent form, especially if associated with laryngitis, an emetic dose of ipecacuanha is a most valuable method of allaying the spasm, 30 gr. of the powdered root, or 20 gr of the root combined permanent paralysis of two limbs by disease; £500 on loss of one limb and one eye following accident, £250 on loss of one limb or one eye by accident, £3 a week on temporary total disablement, and £1 a week on temporary partial disablement, caused by accident, in each case up to 52 weeks in respect of any one accident, £3 a week on temporary total disablement, caused by sickness, without confinement to house (up to four weeks), £3 a week on temporary total disablement caused by sickness with confinement to house (up to 26 weeks for any one sickness), £3 a week during convalescence from sickness (up to four weeks). For these benefits women in Class I (engaged in professional, educational, and clerical duties, and non-hazardous shop risks) pay an annual premium of £6 10s. Death, loss, or disablement through accident or sickness associated with or incidental to child-bearing is not covered. Policies are renewable from year to year by the joint consent of the policyholder and the company, but insurance ceases when the policyholder reaches 55. The age-limit for entrants is 20 to 45. The personal accident and sickness insurance offered to male proposers (Table 4 "Standard") differs so greatly in the details of benefits offered that it is not easily comparable.

Law Accident Insurance Society

This company offers to women, for selected lives only, policy W 3, covering accidents and all sickness. The benefits obtainable for women entering between the ages of 18 and 50, and ceasing when the assured reaches 60, are as follows. Death by accident, £500; loss of two limbs or two eyes, or one limb and one eye £500; loss of one limb or one eye, £250. Temporary total disablement by accident or sickness (*a*) involving confinement to house, weekly £2, (*b*) without confinement to house, weekly £1. Temporary partial disablement by accident, weekly 10s. The weekly compensation is payable up to 52 weeks for accidents and up to 13 weeks for sickness. For these benefits women engaged in non-hazardous business or professional duties pay a premium of £4 10s per annum, and women not engaged in any business or profession pay £6 per annum. Policies are annual contracts. Accidents or illnesses associated with or incidental to child-bearing are not covered.

Medical Sickness Annuity and Life Insurance

Permanent sickness and accident policies are issued to women medical and dental practitioners, subject to the following special conditions. (1) the age at entry must not exceed 35 next birthday; (2) those holding whole-time salaried appointments may only take policies under Table A3 (Women), excluding first three months illness or A3/6 (Women) excluding first six months illness. Under Table A (Women) a doctor or a dentist not excluded by this condition may, for example, insure £6 6s a week for the first 26 weeks of total incapacity and £3 3s a week thereafter up to the age of 65 for an annual premium of £15 8s if her age next birthday is 30. Sickness benefit is payable from the first day of incapacity. Confinement to bed, bedroom, or house is not exacted. The benefits granted include the risk of marriage, but exclude all sickness benefit from the time of pregnancy to three months after the termination of pregnancy and no premium is payable for such period of exclusion. In the event of the assured discontinuing practice for any reason other than incapacity all liability of the company under the policy ceases.

The sickness and accident benefit policy (Table A) offered to male doctors and dentists is comparable as regards benefits received. A man whose age is 30 next birthday would however obtain these benefits for an annual premium of £10 18s 6*d* and the holding of a full-time appointment does not disqualify him for this policy. Moreover the age of entry for male proposers may be as late as 55 next birthday and there is no clause providing for the cessation of liability under the policy if the proposer ceases practice for any reason. Male proposers may also insure under Table A2, receiving the same benefit as under Table A, with quinquennial rebate of 5 per cent of all premiums paid during such period if no claim has been made under the policy during the said quinquennium. This alternative is not offered to female proposers. The special feature of this society's all-sickness and accident contracts for both sexes is that once a policy has been granted it cannot be discontinued by the society except on account of fraud, non-payment of the premium, or permanent residence abroad.

Conclusion

It seems quite possible that the caution exercised by those companies who refuse to entertain proposals from women, even at high rates, is excessive. There can be but few figures available on which the sickness rate has been worked out, and it is probable that the actuarial calculation of the risk from published statistics is not based on figures which give a true picture of the health of the modern working woman. It should be easy to collect information as to the morbidity-rate in nurses at general hospitals. This is a most strenuous occupation, but we believe that sick leave is relatively rare not only during the four years' training, but also among staff nurses and sisters in the permanent service of the hospitals. It is even possible that were women encouraged to insure against sickness the morbidity-rate might improve, since the dread of falling ill is often at least a contributory cause of bad health. We have set out in some detail the facilities which are open to women in the hope that they may be useful to practitioners who wish to provide against this source of anxiety among their patients. It seems likely that if a large number of policies were taken out it might be found possible to drop the rates, for at the moment they must be largely speculative. Further investigations, similar to that carried out by Dr. Fairfield, may yield valuable results.

SOME RECENT STUDIES OF DYSENTERY.

Cultivation of the Amœba.

MANY problems, bacteriological, clinical, and therapeutical, still remain to be solved in dealing with the various forms of dysentery. Recent work, particularly on the bacteriological aspect of the problem, has brought to light some interesting facts. Drs. W. C. Boeck and J. Drbohlav[1] have described the cultivation of the *Entamœba histolytica*. The cultivation of this organism has only once before been carried out successfully by Culter in 1918, and his work has been severely criticised and not hitherto confirmed. The initial cultivation of the *E. histolytica* by Boeck and Drbohlav was achieved by accident. A small amount of fæces was inoculated into two tubes of Locke egg-serum medium as a routine procedure in a study of intestinal flagellates, and on examination of the cultures a few days later many amœbæ were found. These were identified as *E. histolytica* and further culture experiments showed that the best media for the purpose were Locke egg-serum and Locke egg-albumin. An initial alkaline reaction of pH 7·2 to 7·8 is necessary and the optimum temperature is 37° C. The fact that non-parasitic saprophytic amœbæ occasionally occurring in the fæces can readily be grown in artificial media made it very necessary to test the pathogenicity of the organisms cultivated by Boeck and Drbohlav, and these authors therefore carried out a series of animal inoculation experiments with kittens. Rectal inoculations of amœbæ direct from an infected patient and also from cultures produced typical dysentery, ulcerative colitis and hepatic abscess in these animals. The virulence of the organisms was not affected by prolonged cultivation.

Special Articles.

ALL-SICKNESS INSURANCE RATES FOR WOMEN PROPOSERS.

THE excess of sickness among working women over corresponding groups of men in analogous occupations has long puzzled those who would fain believe that it is a myth invented by anti-feminists to keep women out of the labour market As far as the class of teachers goes, Dr Letitia Fairfield, in an address to the London Association of the Medical Women's Federation, which is published on p 5 of our present issue, confirms the fact that the morbidity-rate is much higher among women than among men teachers If confirmation were wanted of the circumstance it could be sought in the very limited facilities offered by insurance companies to women to take out sickness policies The following companies do not entertain proposals from women for policies which include the risk of all sickness Royal Insurance Company, Scottish Union and National Insurance Company, Yorkshire Insurance Company, Employers' Liability Assurance Corporation, Cornhill Insurance Company, Excess Insurance Company, London and Liverpool and Globe Insurance Company, Ltd Certain companies offer accident and sickness insurance to women, but only to those engaged in a profession or occupation Others limit policies still further, accepting only unmarried professional women An analysis of some of the policies open to women, which does not pretend to be either exhaustive or complete, is set out below Only policies which include all sickness are dealt with and only the more important details are included

Eagle, Star, and British Dominions Insurance Co

Since 1919 policies have been issued to women Women between 16 and 60 actively engaged in a business or profession can insure against all accidents and all illnesses under Table 3 at an annual premium of £2, £4, or £8 For the last-named sum the following benefits may be obtained In the event of accident causing (*a*) death, £500, (*b*) loss of one hand, foot, or eye, £250; (*c*) permanent total disablement (other than loss of limb or limbs), £3 a week for 52 weeks, afterwards £50 a year, (*d*) loss of both hands, feet, or eyes, or one hand and one foot, or one hand or one foot or one eye, an annuity for life of £50, (*e*) temporary total disablement, per week up to 52 weeks, £3, (*f*) in the event of illness or disease causing total and irremediable blindness, or permanent general paralysis, £3 a week for the first 26 weeks of disablement, followed by an annuity of £50, (*g*) in the event of illness or disease causing temporary total disablement (with or without confinement to the house), £3 a week, payable for 26 weeks To obtain the same benefits and certain additional ones, of which perhaps the most appreciated must be the benefit named under (*g*) for 52 weeks as against 26, a male proposer in Class I would pay an annual premium of only £6—that is, three-quarters of that paid by a woman engaged in clerical, educational, domestic, and superintending duties, or by shop assistants not using machinery Dancing mistresses, dressmakers (working), gardeners, health visitors, and shop assistants using hand machinery pay 10 per cent extra for this policy, and car-drivers, farm hands, masseuses, nurses, and policewomen 20 per cent extra Marriage on the part of a working woman does not affect her policy, but death, loss, or disablement resulting from child-bearing or from venereal disease are excluded Women not actively engaged in a business or profession can be insured under Table 3A, paying the same annual premium, £8 The risks of accident are evidently considered less great, for example, the death benefit is £600 instead of £500, and for temporary total disablement following accident £4 instead of £3 is payable for 52 weeks Under Table 3A for temporary total disablement due to disease, with confinement to the house, £4 a week is paid up to 26 weeks, without confinement to house, £2 a week up to four weeks

Friends' Provident and Century Life Office

Insurance under Table 2 is offered against accidents and all illnesses to women engaged in a business or profession Policies are issued only to single women and cease upon the marriage of the insured. The benefits obtainable for an annual premium of £6 are (*a*) death by accident, £500, (*b*) loss of two limbs, or of both eyes, or of one limb and one eye, by accident, £500, (*c*) loss of one limb or one eye by accident, £250, (*d*) temporary total disablement by accident, £3 a week for 52 weeks, (*e*) temporary partial disablement by accident, up to 52 weeks, £1 a week, (*f*) temporary total disablement by illness of any kind involving at least one week's disablement, £3 a week up to 26 weeks (*g*) convalescence, £1 10*s* a week up to four weeks The premiums quoted apply to proposers between the ages of 18 and 40 engaged in clerical, educational, commercial, and the like occupations The company issue a "minimum cost" policy to male proposers for an annual premium of £4 10*s* a year—again three-quarters of the premium payable by women For this (*a*) the sum to be received in the event of death resulting from an accident is £500 (*b*) for total disablement due to accident or sickness of any kind a sum of £4 a week is paid, up to a cumulative period of 26 weeks in respect of each accident, or in case of sickness to a cumulative period of 26 weeks in respect of all illness occurring in any one year of insurance: (*c*) medical and surgical fees are paid up to a sum equivalent to one-sixth of the benefit payable in respect of temporary total disablement

Ocean Accident and Guarantee Corporation

Women between 18 and 50, married or unmarried, who are engaged in a profession or business and incurring average risk can for a premium of £9 9*s* a year obtain the following benefits In case of accident causing death, or loss of hands or feet or eyes, or of one hand or foot and one eye, or of one hand and one foot, £600. loss of one hand or foot or eye, £300, total disablement per week, £3, partial disablement, per week, 15*s* Permanent total disablement not otherwise compensated For the first 52 weeks of disablement, per week, £3, for the following ten years an annuity of £50, which annuity is also payable in the case of total and irremediable blindness, or permanent paralysis of two limbs, not caused by accident Total disablement caused by certain specified illnesses, per week, £3, total disablement for not less than seven days caused by any other sickness, per week, £3 Death or disablement consequent upon pregnancy and childbirth is excluded The weekly compensations are payable up to 52 weeks and confinement to the house is not exacted

The all-sickness and accident policy offered to male proposers by this company gives exactly parallel benefits for an annual premium of £6 6*s* to those in Class I occupations (including medical practitioners) The sole difference in the prospectus appears to be that the limit of age for male entrants is 55 (against 50) The difference of premium is as two to three between males and females in this company —that is slightly less favourable to the females than in some of the others, but, on the other hand, no extra benefits are offered to the males

London Guarantee and Accident Company

This company offers all-sickness and accident insurance to women engaged in professional, commercial, and industrial life The benefits include the following £25 on death from accident or sickness; an annuity of £50 on permanent disablement through loss of two limbs or two eyes, or on permanent loss of sight of two eyes by disease, or on finger-prints coincided in 32 ridges with prints found on a broken window-pane at the theatre The accused man's finger-prints were taken (with his consent) in court, and, though he denied his guilt, the jury found the evidence of identification adequate and convicted him Possibly more use of the system would be made in criminal trials if it were not regarded as unfair to ask the accused to allow his finger-prints to be taken It is, of course, objectionable to prove a man's finger-prints from records in the possession of Scotland Yard while his innocence or guilt is being determined, because such an action gives the jury a hint that he is a man of bad character who has already been convicted before The law does not allow such hints to be given Not many months ago goods were stolen from a warehouse, a woman standing opposite the premises had noticed a man with a hand-cart whom the police supposed to have been the culprit She was shown by a detective several photographs of convicted thieves and she picked out one of the portraits as that of the man she had seen At the trial, during her examination-in-chief, the prosecution most improperly asked questions which elicited the fact of her having identified the accused man from police photographs The man was convicted, but the Court of Criminal Appeal quashed the conviction, the Lord Chief Justice severely criticising the irregularity which had prevented the accused from having a fair trial Similarly, no doubt, evidence identifying a man by finger-prints purporting to come from the archives of Scotland Yard (and therefore indirectly establishing the fact that he was a man of bad character) would prima facie be inadmissible

The main value of the finger-print system in criminal cases lies in the preliminary stages of investigation, or in proving the career of a prisoner after he has been convicted and before he is sentenced Another use of the system was disclosed lately at an inquest in Poplar A woman's body was taken from the Thames on June 7th She was unidentified until the police took her finger-prints post mortem and thereby traced her, her previous career having been known to Scotland Yard The coroner, Dr R L Guthrie, asked if the taking of finger-prints in the case of unknown persons was not a new practice The detective-inspector replied that it had been done for five or six years, but that this was the first case recorded in which a person had thus been identified after death A few days later Dr Harvey Littlejohn, professor of forensic medicine in Edinburgh, corrected the statement In April, 1913, it appears, a man was found dead in a quarry near Edinburgh The body being unidentified, the professor suggested the taking of finger-prints on the chance of the deceased having been known to the police Scotland Yard was consulted, and by return of post replied giving the man's name, alias place of birth, age, height and complexion and the colour of his hair and eyes The reply was accompanied by a photograph which left no doubt of the identity of the deceased As Prof Littlejohn observes, the incident was a tribute alike to the efficiency of the finger-print department of Scotland Yard and to the value of the method in the identification of the dead A later letter to the *Times* from the Chief Constable of Oxford mentions a case where a man apparently concerned in certain frauds in that city died suddenly and was identified with the aid of the finger-print records of Scotland Yard The practice of taking the finger prints of unidentified bodies is stated to be common in India

Charge under the Venereal Disease Act

The Venereal Disease Act forbids, as is well known, the advertisement of remedies and the offer of treatment by persons who are not qualified medical practitioners Prosecutions under the Act have been remarkably rare Mr H G Muskett appearing for the police in a recent case in the Clerkenwell police-court, stated that it was the first of such prosecutions which he had had to undertake since the Act began to operate in May, 1917. The summons was against Percy John Murrell, trading as the Orion Chemical Manufacturing Company Mr. R E Dummett, the stipendiary magistrate, imposed a fine of £20 and ordered the payment of £5 5*s* costs, with the alternative of two months' imprisonment It will be recalled that Lord Trevethin's Committee in 1923 recommended that the law be altered to allow properly qualified chemists to sell approved disinfectants as a protection against venereal disease, the sale being accompanied by approved instructions A Bill to effect this amendment of the 1917 Act is now before Parliament

Partnership Disputes

During a recent partnership dispute between doctors Mr Justice Horridge, trying the case with a special jury, asked if some arrangement could not be reached before the case proceeded further, as both parties were on the high road to ruining themselves They might be rich men, but he should have thought it was ruin for two doctors to go on fighting a case and be away from their patients for days Whatever the result might be, it must be bad for their practice In deference to the judge s suggestion counsel conferred, but the case proceeded Next morning, however, a settlement was announced As both plaintiff and defendant withdrew the charges which they had placed upon the pleadings, there is no occasion to deal with the evidence It is sufficient to explain that the pleadings indicated that two medical men had entered into partnership in London, one having agreed to pay £2500 for a half share in the practice of the other The purchase price was duly paid, except for the final £500, for which sum judgment had been signed The purchaser counter-claimed for damages on the ground of fraud and misrepresentation (mainly as to the value of the practice), he also claimed the return of his £2000 and the rescission of the partnership agreement Thereupon the other party pleaded that the purchaser suffered from chronic recurrent alcoholism, and was on that account incapable of constantly and regularly performing his part of the partnership agreement, and that, therefore, the court should dissolve the partnership When the case was settled, each side withdrew its charges and stated handsomely enough that it was satisfied that they were without foundation. There is, therefore, no more to be said than the somewhat platitudinous reflection that it is a pity that such charges should be solemnly made before judge and jury if they can be whole-heartedly withdrawn within 24 hours, and that the publication of disputes of this kind does good neither to the practitioner nor to the profession.

How are incidents of this kind to be avoided? If the court is likely to intervene to press a settlement upon the parties—a contingency by no means unlikely in cases of this nature—what is the good of running up lawyers' bills? Here were two partners each asking for dissolution of a partnership relation which at the moment was evidently intolerable to both Why could they not save themselves friction, costs, and publicity by a simple mutual agreement to dissolve? The purchase money was, no doubt, a stumbling-block · but, if the parties could have referred this point to some umpire in whom both had confidence, a reasonable award by him as to the proportion of the purchase money to be retained or returned would have settled the dispute and left the parties vastly better off than after the briefing of fashionable counsel Once personal charges of fraud or drunkenness are launched, a professional man must fight them with his last penny But cannot disputes of this kind be submitted to some professional tribunal? Is there no means by which doctors entering into partnership can bind themselves to accept such arbitration? The presidents of the professional bodies of engineers and of architects are frequently called upon to appoint arbitrators (though not perhaps particularly in relation to

Immunisation against Bacillary Dysentery.

The production of immunity against dysentery, upon lines which proved so successful in the case of typhoid in the late war, has long engaged the attention of bacteriologists. It is, perhaps, not a clamant necessity in ordinary conditions of life, but becomes one the moment any great upheaval, such as wars, famines, and earthquakes, causes a violent disorganisation of normal social conditions. A successful method of bringing about active immunity to this disease would be one to be held in reserve against emergency, or only applied under present conditions in this country in asylums or institutions in which epidemics of bacillary dysentery might occur. None the less, the problem is an important one, and in countries less happily situated hygienically a pressing one. The difficulty in the way of applying the method used for typhoid, without modification, is the extreme severity of the reactions set up by the injected organisms; these are exceedingly unpleasant and unlikely to be tolerated by the average population. From time to time various attempts have been made to modify the toxic properties of the organisms without interfering with their antigenic value, but none of these has as yet gained general recognition. In the current number of the annals of the Pasteur Institute[2] J. Dumas, Ramon, and S. Bilal put forward a further method, which has been suggested by studies upon diphtheria anatoxin. It has been found by Ramon that diphtheria toxin treated with formol becomes modified, so that its toxic properties are destroyed, but its capacity to provoke antitoxin production when injected into the animal body, and to combine with antitoxin is retained. In working with dysentery the anatoxin is prepared by treating a toxic filtrate of a 15 days old broth culture of *B. dysenteriæ* Shiga with formalin at incubator temperature, under which circumstances the toxin is found to become less potent and finally, at the end of about one month, to be practically non-toxic. With regard to the antigenic properties of this substance its injection into animals appears to result in both an antitoxic and antibacterial immunity, whilst in its use in immunising horses, for the production of antidysenteric serum, it has not been found to produce the severe reaction occasioned by the unaltered toxin although giving rise to an efficient therapeutic serum. In the human subject the method has only been tried on a small scale, and whilst it is certain that some reaction results from its use, this is stated to be less than that observed after antityphoid inoculation. The authors show praiseworthy caution in stating that the success of their procedure cannot be assumed until it has been extensively put into practice under epidemic conditions.

Castor Oil versus Saline Aperient.

Dr. A. J. Boase[3] has described the use of castor oil as opposed to saline aperients in the treatment of bacillary dysentery in Kenya. This treatment was introduced in that country in 1924, and Boase has investigated 117 consecutive cases of bacillary dysentery occurring among convicts with regard to these two main methods of treatment. Of these 45 were treated with saline aperients in the routine fashion with a death-rate of 8.8 per cent. and a relapse-rate of 29 per cent. The remaining 72 cases received two ounces of castor oil on admission and on subsequent days 1 drachm hourly for eight doses until the day when the stools ceased to show blood and mucus. This usually occurred about the third day and a saline purge was then given to relieve any constipating effect of the castor oil. Among these cases the death-rate was 2.8 per cent. and the relapse-rate 11 per cent. These figures certainly seem to indicate the value of castor oil at any rate in this particular epidemic. There appears to be some scientific basis for this form of treatment, since absorption of toxins from the small intestine is undoubtedly an important factor in the intoxication produced in dysentery, and a drug which will hurry on the intestinal contents rather than lead to even the slightest delay is bound to be beneficial. An important point with regard to the castor oil treatment lies in the diet which is not restricted, as occurs when the saline aperients are used, but allowed to be almost full. The number of patients treated is certainly small, but the results point to an important innovation in the treatment of bacillary dysentery.

Serum Treatment of Bacillary Dysentery in Children.

In Australia Dr. R. Webster and F. E. Williams have been examining the dysentery bacillus in its relation to the so-called "summer diarrhœa" of infants and young children.[4] Although the dysentery bacillus as a cause of infantile diarrhœa does not appear to be nearly as common in the Commonwealth as, for example, in America, yet Australian work indicates that other parts of the world beside America find this type of the disease of some importance. The dysentery bacilli isolated from the stools of infants and young children over a period of nearly three years were mostly mannite fermenters, the Shiga group being a negligible factor. Of the Flexner group the "W" strain appeared most commonly, while the Sonne bacillus also assumed importance, especially at certain portions of the period under review. The mortality-rate for the various members of the Flexner group did not appear to vary with the strain, being in the neighbourhood of 50 per cent., for example, in the season 1923–24. Such a high mortality-rate makes the question of specific serum treatment of great importance, and Dr. Webster deals with this in the second part of his paper. Serum injected after a lapse of four to five days of illness appeared to be quite ineffective in reducing the mortality or modifying the course of the disease, while in six cases in which serum therapy was instituted within 48 hours of the onset of the disease recovery took place in five cases. Such results illustrate the need for early diagnosis, and Dr. Webster emphasises the appearance of blood and mucus in the stools of such cases as being strong presumptive evidence that the dysentery bacillus is the cause. A prompt bacteriological report is also necessary, and Dr. Webster has elaborated a technique which enables him to identify the dysentery bacillus in the same time as a throat swab can be reported on for the diphtheria bacillus. Polyvalent serum has been used up to the present, but the suggestion is put forward that monovalent serum for the "W" and "V" strains of the Flexner group should be prepared and used since these appear to predominate, and a method for the rapid identification of the serological race of an organism is now under consideration.

MEDICINE AND THE LAW.

Identification by Finger-prints.

THE law courts, at any rate for the purposes of criminal trials, often show a reluctance to accept results which science has established. The system of identification by finger-prints has provided an example of this hesitation. In Rex *v.* Chadwick, a case tried at Birmingham in 1908, the accused was charged with burglary. The burglar had left finger-prints upon a champagne bottle and it was proved in evidence that they coincided in no less than 12 of the ridges with the finger-prints of the accused. The judge advised the jury not to accept this evidence; the jury, however, found the accused man guilty nevertheless. A clearer example of the value of the system occurred in 1916 at the Old Bailey when a man was charged with breaking into Sadler's Wells Theatre and stealing Treasury notes. It was proved that his

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Pan-American Red Cross Conference

THE second pan-American conference of the Red Cross opened at Washington in the last week of May. Organised by the League of Red Cross Societies: it was attended not only by representatives of the Red Cross Societies of North and South America but also by many allied organisations on these continents and by sister organisations from across the seas. It was pleasing, for instance to hear a report from Mr Hirosi Saito, a delegate of the two and a half million members of the Red Cross Society of Japan. The League of Red Cross Societies has been skilful in building an efficient organisation with a minimum of rigid regulation and red tape. As a result the representatives at the conference demonstrated a variety of interests as well as of nationality. At the same time the discussions all centred upon some phase of the established peace time programme of the Red Cross: struggle against disease rescue in disaster. or education for health and goodwill

The Department of Hygiene in the Republic of Paraguay has lately concentrated its efforts on the problem of leishmaniasis americana a disease which ranks in importance there with tuberculosis malaria, and syphilis While appealing to research workers to help them solve the problems of its ætiology they have not awaited a response before establishing preventive and curative stations The Paraguayans are at present advised to bathe the body at the end of each day's work to treat all bites of insects with antiseptics and to take early medical advice on pustules which may be leishmaniasis in an early stage The present treatment consists in cauterisation with silver nitrate followed by injections of tartar emetic.

Under the ægis of a national nursing association special tuberculosis nurses have been trained in Cuba. and are doing efficient work in the hospital the dispensary and the home As a result of their educational campaign there has been a marked improvement in the standards of hygiene throughout the country. The Red Cross Society of Colombia has established among other things, a health centre where maternity care is successfully given The great event at this centre takes place on Tuesdays and Fridays of each week when 'a select group of ladies . and some others who come with less regularity receive the dirty and malodorous children which the mothers bring there for that purpose, bathe them rinse them. dress them with new clothing and give them to their mothers completely transformed'

The Mexican Blue Cross

An unusually interesting institution is the Mexican Blue Cross founded in San Antonio Texas U.S.A. on Oct 12th, 1919 Its object is to bring succour to the Mexicans—over a million of them—who live in the southern parts of the United States, and it has at the present time 269 outposts established in six southern and western States Its work, as picturesquely described by its secretary and founder, Senor Jesus Franco includes —

'Distribution of food and clothes: providing doctors and medicines to the sick: visits paid to the hospitals and jails in which compatriots or persons of Spanish speech, are recluded providing them with comforts and sending them fruits, candies &c. Those who die without the attention of their relatives, leaving no resources are piously buried by Sisters of the Mexican Blue Cross the expenses being covered by the institution. Those that on account of sickness or disgrace are unable to work, and for their lack of means are obliged to go back to their families in Mexico are sent by the Mexican Blue Cross. . . The Mexican Blue Cross also labors in a moral way, inculcating a high spirit of sentiment of fraternity and of love toward men without any di while at the same time we commend to our men a high and eternal gratitude toward th pitable country (the United States). and the obse of a blameless behavior. based in the respect o law and righteousness"

The work of such an organisation must sur promote understanding and cement friendship betwe Mexico and the United States

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

Paying Wards in Hospitals.

THE question of community hospitals or in plainer English the establishment of paying wards in public hospitals, is much under discussion, and here as elsewhere it presents great practical difficulties. These are partly due to the methods of hospital administration in vogue, which differ materially from those in England From 1853 to 1876 when the country was divided into provinces, hospitals were administered locally. From 1876 to 1886, after the abolition of provinces. there was great lack of uniformity in the hospital management. the amount of voluntary contribution varying in different districts: in some it was quite considerable In 1885 and subsequently Acts were passed establishing the present system which is briefly as follows: The country is divided into some 40 districts, each under its own hospital board popularly elected. Each board imposes a rate according to the estimated cost for the year, on which it receives a pound-for-pound subsidy from the Government This method may have equitably distributed the cost of hospitals over the community, but it has had the effect of abolishing voluntary subscriptions. though handsome donations have been made for specific purposes The hospitals were originally established for the indigent (of whom there are now very few) and for those who can pay a maintenance fee of 9*s* a day In most of them the medical staff is honorary, although in some districts small stipends are offered.

This restriction of the hospitals to the poorer section of the public is not likely to remain for in 1924 the Government, following the decision of a Hospital Commission definitely declared that the public wards of the hospitals were available for rich and poor alike which has raised a very live issue for their honorary staffs Abuse of hospitals is not unknown here, and in view of the growing need for hospital accessories—such as X rays and bacteriological investigation—in private practice. and the great convenience of public hospitals as affording them, a movement is on foot to establish paying wards This movement started long ago but has been considerably stimulated by the Government pronouncement In 1920, at the first congress after the war, the New Zealand branch of the British Medical Association passed a resolution in favour of paying wards, and in spite of some notable dissentient divisions it has held to this policy. Since the visit of Dr William Mayo and other distinguished Americans to New Zealand and the visit of New Zealand doctors to the American College of Surgeons in 1924. the American conception of the community hospital has been extensively advocated and Dr McEachern of the American College has toured the Dominion on behalf of the scheme as applicable to this country. He finally addressed a joint meeting of members of the Government Health Department the hospital boards and the B.M.A. and advised a reduction in the number of the hospital boards the establishment of a non-political Board of Control of hospitals the encouragement of voluntary subscribers with representation on the management and the construction of hospital accommodation for all classes of patients, according to their ability to pay.

professional partnerships), the legal profession has machinery by which disputes between the two branches can be referred to the Bar Council for final decision Has the medical profession sufficiently considered the provision of like facilities? It is lamentable enough when in the divorce court husband and wife launch charges in the endeavour (often frustrated) to dissolve a union which is irksome to both It is ludicrous that the parties to a medical partnership, a form of union neither so personal nor so permanent, should follow suit

Many partnership disputes could be avoided at the outset If books are properly kept, and if intelligent inspection of them is obtained, it should rarely be possible in an honourable profession to plead fraud or misrepresentation as to the value of a practice Lawyers and accountants can be of use here in advising upon figures or the absence of figures But they can give no advice upon incompatibility of temperament, nor does the law provide any elastic method of dissolving partnerships which fail for purely personal reasons The Partnership Act terminates partnerships automatically in certain cases —death, bankruptcy, illegality, expiration of agreed term, &c —and allows the court a discretion to dissolve partnerships in certain other cases The court may decree a dissolution if a partner—

(*a*) is a lunatic, or

(*b*) becomes in any other way permanently incapable of performing his part, or

(*c*) has been guilty of such conduct as in the opinion of the court (regard being had to the nature of the business) is calculated to affect prejudicially the carrying on of the business, or

(*d*) wilfully and persistently commits a breach of the partnership agreement or otherwise so conducts himself in matters relating to the partnership business that it is not reasonable for the other partner or partners to carry on the business in partnership with him, or again

(*e*) when the business can only be carried on at a loss, or

(*f*) whenever circumstances have arisen which, in the opinion of the court, render it just and equitable that the partnership be dissolved

In cases (*b*), (*c*) or (*d*) the court will not act at the instance of the partner who is to blame There has not been much decision as to the circumstances which would make dissolution "just and equitable" under (*f*) Prejudicial conduct under (*c*) depends upon the nature of the business, adultery by a partner would not justify the dissolution of a partnership of merchants, but immorality by a member of a medical partnership has been held to suffice Wilful persistent breach of contract under (*d*) has been explained to mean "studied, prolonged, and continued inattention to the application of one party calling upon the other to observe the contract" Unreasonable conduct does not mean mere squabbling and ill-temper, but a state of complete and permanent animosity making an impassable breach between the parties and destroying mutual confidence

Thus Parliament and the judges have laid down the lines along which partnership disputes will be decided in actions at law Is the procedure elastic enough? If not, what better machinery can be devised within the profession? Arbitration, as contrasted with legal proceedings in the law courts, has two drawbacks First, it tends to be unexpectedly expensive, especially when it involves audience by legal representatives, secondly, the law courts are jealously inclined to seek occasions to intervene unless the parties can eliminate this intervention by some specially wide and binding undertaking to accept the arbitrator's award on all points as final But arbitration possesses the great merits in matters like medical partnership disputes that it avoids the washing of dirty linen in public

EPSOM COLLEGE THE ANNUAL MEETING

THE annual general meeting of subscribers to the Foundation was held at the London Offices, 49, Bedford-square, W C, on June 25th, Dr Raymond Crawfurd presiding The principal business before the meeting was the announcement of the result of the elections to the pensionerships, annuitants, and foundation scholarships Dr Crawfurd said that the number of votes gained by certain of the successful candidates implied the accession of new subscribers to the Foundation In congratulating those who had been successful he asked the meeting to sympathise with those who had not and pointed out that the ideal before the Foundation was to provide these benefits for all who stood in need of them The secretary read the names of the successful candidates as follows —

"Highett" "Pugh" and Ordinary Pensionerships

	Votes		Votes
Johnson Everard S R	12 490	Matthews, Guy A	6562
McDonald Charles F	12 083	Adams, John E	6072
Galpin Richard J L	11 066	Hudson, Eric J	5159
Blakeway Michael G	8692	Cook, Robert S	4315
Williams, Paul G	6671	Rew, Kenneth G R	3800

A meeting of the Council followed upon the annual general meeting, when Dr Crawfurd resumed briefly the activities of the past year The school, he said, had now 345 boys, and the raising of the salaries of the teaching staff was reflected in the scholarship successes. He was glad to say that in the near future the British Medical Association and the Medical Insurance Agency would be represented on the Council He alluded to notable acts of benevolence by which they had benefited mentioning the gift of £1000 from Mr William Tinker and the institution of a new exhibition arising out of a gift from Dr H R Mosse The Council, he said, had spent largely during the year but had not been forced into debt by doing so A chemical block had been erected which would be opened by Lord Grey on next Founder's Day, July 24th, the library had been completely transformed to serve also the purpose of a reading room, and large and necessary structural changes had been made in the lower school buildings The Works Committee had undertaken the centralisation of the heating of the building, and there had been a complete conversion of the lighting scheme which now depended upon electricity alone These things in the main accounted for recent expenditure, and he went on to outline as the structural scheme of the future the building of a new infirmary, pointing out that the existing building, though unfitted for a modern infirmary, could be transformed into a boarding-house offering accommodation for some 40 more pupils He mentioned that among the boys themselves there had arisen a movement for the erection of a new games' pavilion, and large as the sum required was he had reasonable hope that it would be forthcoming

A vote of condolence was passed with the relatives of Sir Henry Morris, for many years the zealous treasurer of the College

There followed the re-election of certain members of the Council retiring under time-limit and of the auditors, the election of Mrs H G Tetley and Dr E Climson Greenwood as vice-presidents, and the election of Sir William Hale-White as treasurer of the College in succession to Mr H S Pendlebury, for whose services a hearty vote of thanks was recorded

Given the money, a voluntary hospital could establish such a scheme to-morrow, if it chose; but the difficulties in adopting the policy in municipal hospitals are evident when details are discussed The ratepayers, not the doctors, contend that any ratepayer has a right to enter his own hospital, and that all must enter on equal terms, the hospital boards decline to incur expense in building wards for the convenience of doctors in their private practice, and the cry is raised of " class distinction " (which applies equally to the provision of first- and second-class carriages on the Government railways) The Minister of Health has spoken unfavourably of the scheme on at least two public occasions, on the ground that it would lead to undue control of the hospitals by the medical profession, and perhaps he voices the public opinion The doctor, on the other hand, appears to have determined that he will not act for the existing hospital patients except in an honorary capacity—that is, he will not become a paid servant of a hospital board He declines to treat persons in an honorary capacity who can pay his fees, and he finds and fears an increasing tendency for such persons to enter public hospitals on account of their accessory advantages He sees a solution for all these difficulties in wards for paying patients, but he is not at present very clear as to how they are to be provided

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH

The following table gives some of the health statistics for 1925 of a group of districts We comment below on the reports recently issued from the medical officers of health

Name of district	Estimated mid year population (R G)	Birth rate	Death rates per 1000 of the population					Death rates per 1000 births	
			All causes	Tuberculosis	Cancer	Resp diseases with influenza	Heart disease	Infant mortality	Maternal mort from childbirth

Southport

Dr G C Barnes describes his area as a bed of blown sand resting on peat, which, in its turn, rests on laminated blue clay Although the lower strata are subsiding, the loss is more than made good by the sand derived from the Mersey, and land is rapidly being reclaimed on the foreshore Thus, since 1921, 30 acres have been reclaimed and form an extension to the municipal golf links High banks of house refuse are constructed to exclude the sea and are covered with soil and sown with grass seeds When the banks have been formed, the area reclaimed is filled in with refuse covered with sand and sown During 1925 630 new houses were erected Generally speaking, the housing conditions are good, but there is still a lack of houses for manual workers and other persons with small means The cost of labour and materials also interferes with the repairing work. The birth-rate has declined considerably during the last quinquennium In 1921 there were 1106 births and in 1925 only 973 The percentage of deaths at various age-periods has altered Thus the percentage of deaths under 1 year was 8 1 in 1921 and is now 6 3, while *the percentage of deaths* over the age of 65 has gone up from 48 8 in 1921 to 52 3 in 1925 The isolation hospital is reported to be " both obsolete and tumble-down," but nevertheless Dr Barnes is able to give credit to the nursing staff for obtaining excellent results A peculiar feature of the scarlet fever recently dealt with has been the number of relapses or second attacks " The cases referred to are those in which the patient has had an unquestionable and characteristic attack of scarlet fever, often of decided severity, and in which the second attack of undoubted scarlet fever occurs during the treatment " The second attack was, as a rule, of moderate or slight severity At the tuberculosis sanatorium trial has been made of Dr Samuel H Stewart's lung splint with encouraging results, and it is suggested *that this method has advantages over treatment by* artificial pneumothorax Dr Barnes again comments on the difficulty in getting in touch with cases of pulmonary tuberculosis at an early stage of the disease and supports his comments with the history of some typical cases He concludes with a list of the early signs, which should have a good effect in bringing available resource for diagnosis into action without delay *Antenatal work makes considerable progress* Thus the births numbered 973, and 177 expectant mothers visited the antenatal clinic at the municipal maternity hospital Dr A S Garden, the obstetrician-in-charge, says the attendances at the clinic are most satisfactory

An unusual feature of the sanitary work of Southport is the flushing of private drains at the public cost. *This apparently originated* in the large number of objectionable waste water-closets which needed special attention to keep them clean The practice was discontinued in the early years of the war, but was resumed in October, 1923, and cost the local authority £1761 in 1925 Dr Barnes thinks this public flushing of private drains may have an educative effect upon the householder The water-supply is derived from wells over 200 feet deep, maintained by a water board which supplies Southport, Formby U D, and West Lancashire R D The temporary hardness is 23 7 and the permanent hardness 11 6 Dr Barnes describes the water as exceptionally pure An atmospheric pollution table shows that Southport comes out well in comparison with London and industrial districts

Watford

Since the new Milk Act came into force the council have decided to take samples at least twice a year from every milk-supply coming into the town, and they have also appointed a veterinary inspector to examine the herds in the two cowsheds situated in the borough The demand for designated milk is increasing Dr W J Cox reviews the housing position in Watford *In 1923 a municipal scheme for the* erection of 953 houses was completed At the beginning of 1921 the medical officer of health estimated the need for houses at 1000 At the end of 1923 there was still a waiting-list of 1000 families Since the completion of the municipal scheme this waiting-list has gradually increased to 1650 in March, 1926 Private enterprise does not cope with the demand for working-class houses Two municipal schemes are therefore on foot—namely, to provide 124 houses on the Harebreaks estate and 48 on the Wiggenhall estate In addition to this 74 houses are being built on the latter estate for rehousing slum-dwellers Progress has been made in the demolition of condemned houses, the worst slum having now been entirely demolished, 30 years after its condemnation by the medical officer of health of that time Dr Cox states that during the *last five years* the maternity and child welfare work has been developed by the addition of a dental clinic and the assistance of the orthopædic centre of the Red Cross Association has proved very useful an increasing number of infant cases being referred to it every year. The mothers attending the antenatal clinic have increased from 175 in 1921 to 321 in 1925, the total births in the borough being 847 in the latter year The infants' home at Little Nascot was originally opened as a crèche during the war. At first it was used for both ailing and normal infants. It has been found, however, that certain parents make a convenience of the home for getting rid of their children. In future, therefore children will be returned home when their health is established and the home will be made available for ailing children in districts outside Watford The school report shows that as a rule parents in Watford respond promptly by obtaining treatment for their children when defects are pointed out The dental scheme in the schools has made steady and satisfactory progress during the past five years

Woking Urban District Guildford Borough, and Guildford Rural District

Dr. R. W. C Pierce reports that the fever hospital at Woodbridge, Guildford which serves his three districts and also the borough of Godalming and the rural district of Hambledon is inadequate. There are no small wards for complicated cases or cases requiring isolation Before the war plans had been prepared for a new ward for diphtheria and four single-bedded wards but the scheme was abandoned both then and after the war for reasons of economy. Dr. Pierce is convinced of the utility of an isolation hospital for diphtheria but is impressed with the objections to so-called hospital isolation for scarlet fever He is of opinion that cases indistinguishable from scarlet fever, but which are not true scarlet fever, are frequently admitted to hospital and there develop true scarlet fever. He thinks, also, that mild cases of true scarlet fever are apt to become more severe as the result of admission to a general fever ward. He concludes, therefore, that the only really satisfactory hospital method of treating scarlet fever would be to isolate each case in a separate cubicle During 1925 the average detention of diphtheria patients in Woodbridge hospital was 49 days and of scarlet fever patients 60 days In each case the stay might be shortened if unhealthy tonsils were removed, but in diphtheria convalescence the anæsthetic has its dangers and in scarlet fever operation could not safely be undertaken until all inflammation of the throat as resulting from the fever had subsided. There is still a great scarcity of cottages in the Woking district, and Dr. Pierce favours the erection of steel cottages of the Weir or Atholl type. In the Woking district many of the houses have large back additions which interfere with the lighting of the living-room, and a by-law is needed limiting the extent of this back addition In Guildford borough 406 municipal cottages have been built since the war, and the arrears of rent are strikingly small. Dr. Pierce has reason to believe, however, that the tenants are only able to pay the high rents by stinting themselves of food and necessaries The need for cheaper dwellings is imperative and the 22 cottage flats erected last year were enormously appreciated. Dr Pierce also thinks that the small percentage of rents in arrears indicates that ability to pay the rent is the chief qualification considered in the selection of tenants rather than need of accommodation. In Guildford rural district the council formulated a scheme in 1919 for the erection of 256 cottages: 195 of these have been erected but there is still a scarcity, made worse by the acquisition of existing cottages by week-end visitors In one parish the number of cottages built in recent years is actually less than the number converted into "week-end cottages" In all these districts considerable attention is being given to the improvement of the milk-supply.

Thrapston Rural District.

A quarter of Dr. A. McInnes's district population 82[illegible], is in Huntingdonshire, the rest in Northamptonshire Two cases of encephalitis lethargica were notified The one, a man of 29, died from septic trouble and the diagnosis was doubtful The other, a boy of 12, recovered, and it is stated by his schoolmaster that since restarting school this boy, previously rather dull mentally, has developed quite a capable mathematical brain

The one case of puerperal fever notified ended fatally, the patient was confined in a low-lying damp house with a cattle-yard behind it During the last nine or ten years impetigo contagiosa has been common among the children living in the immediate neighbourhood The public water-supply at Woodford was found to be polluted with *B coli* Investigations showed that the well was faultily constructed, permitting easy contamination by surface water. The mouth of the well was raised and the well was given an impervious surround down to the clay. Dr McInnes mentions that there is much room for improvement in the district as regards cleanliness in milk production.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 19TH, 1926.

Notifications—The following cases of infectious disease were notified during the week:—Small-pox 1[illegible] (last week 201) scarlet fever 1412; diphtheria, 808, enteric fever, 53 pneumonia 572; puerperal fever, 50; cerebro-spinal fever 5 acute poliomyelitis 9 encephalitis lethargica 42 continued fever 1, dysentery 12, ophthalmia neonatorum 107 There were no cases of cholera, plague or typhus fever notified during the week.

Deaths—In the aggregate of great towns including London there were 2 (0) deaths from enteric fever 37 (5) from measles, 4 (4) from scarlet fever 21 (1) from whooping-cough 24 (6) from diphtheria 41 (11) from diarrhœa and enteritis under two years of age and 38 (4) from influenza. The figures in parentheses are those for London itself.

THE DREADNOUGHT HOSPITAL FOR SEAMEN.—On June 23rd, at Greenwich Lord Devonport laid the foundation-stone of a new building to be a nurses' home for the hospital with accommodation also for massage, X ray, and ultra-violet light treatment This, Captain Sir Arthur Clarke chairman of the board explained had only become possible since Lord Devonport when Food Controller, had determined to start a fund to commemorate the work done by seamen for the country in the war and had raised £250,000, one-third for endowment while the Admiralty had let the hospital have the ground on the Greenwich Hospital School side of the road on very favourable terms.

INTERNATIONAL EXHIBITION IN BUDAPEST—An exhibition was opened in Budapest early in June which will continue until the end of August. Its promoters have tried to cover the whole realm of hygiene and public health and there are sections dealing with every branch of domestic and sanitary science. In addition the exhibition contains many diversions and the visitor may enjoy the amenities of one of the most beautiful cities in Europe. A booklet has been issued entitled "Three Days in Budapest" which can be purchased from all travel bureaus for 1 million Hungarian crowns (about £3 sterling) and which contains coupons entitling the holder to a Hungarian visa at half price to reduced fares on the Hungarian railways, to hotel accommodation in Budapest for three days, and to many other facilities.

DONATIONS AND BEQUESTS.—Mr. Isidore Silverberg, of Sefton Park, Liverpool, besides bequests to Jewish and other institutions, left £1200 to the Hospital for Consumption and Diseases of the Chest as to £1000 to endow two Silverberg beds either at Mount Pleasant or at Delamere, and the income from £200 to provide the usual Christmas tree; £1000 to the Liverpool University as an Isidore Memorial Fund: £300 to the Norwood Jews' Hospital and Orphan Asylum; £500 to the National Council for Combating Venereal Diseases: and £250 to the Queen Victoria District Nursing Association.—Mr. Henry Johnson Mason of Halesworth Suffolk, formerly of Bingley, Yorks, left £1000 to Dr Maurice Alan Cassidy, of Montagu-square, W., "in recognition of his kindly and unremitting attention."—The late Mr. John Stuart, C.B.E., of North-side Clapham Common, S.W., and of Stonehurst, Ardingly, Sussex, left by will £1000 each to the Royal Infirmary, Edinburgh, and the King Edward's Hospital Fund.

NON-SPECIFIC PROTEIN INJECTIONS IN CHRONIC ARTHRITIS

To the Editor of THE LANCET

SIR,—Dr Yeoman's article in your issue of June 26th is worthy of most careful study and he is to be congratulated upon the success which has attended his use of injections of foreign proteins

Two sentences in his communication call for comment "Antibodies which have disappeared after an infection return to the serum after any procedure that increased the body temperature' 'Perspiration is an important factor, for the patients who derive the greatest benefit have the most profuse perspiration" From these two observations it would appear possible that the good results which this mode of treatment can produce are dependent mainly, if not entirely, upon the two factors of fever and sweating

For many years Wilde has claimed that rheumatic affections can be cured by the simultaneous production of artificial fever and sweating Those who have studied his work and treated patients in accordance with this view can claim startlingly good results For the production of fever and sweating there is no need to subject a patient to the pain and general disturbance that follow intravenous injections of vaccines Equally good results follow the enclosure of a patient in a warm moist atmosphere for half an hour once or twice a day, or the use of hot packs Such measures produce a rise of temperature of 3° to 4°, profuse acid sweating, and a speedy relief of pain and disabilities such as Dr Yeoman describes They entail neither admission to hospital nor confinement to bed and can be carried out at home without undue disturbance of daily routine They may be slower in their action than intravenous injections of foreign matter but are none the less certain of success if properly carried out Such treatment is not a cure-all, mechanical disabilities of joints may necessitate local mechanical measures in addition, septic foci must be dealt with if they are delaying cure and perpetuating disease and in some cases specific vaccines may be indicated—e g, in gonorrhœal rheumatism—but the main elements of treatment are to make the patient feverish and to make him sweat

I am, Sir, yours faithfully,

C E SUNDELL

TUBERCLE BACILLI IN TUBERCULOUS PUS

To the Editor of THE LANCET

SIR,—I should like to record a few critical remarks on a paper with the above title by Dr A D Gardner, which appeared in THE LANCET of June 5th I do so chiefly to draw attention to the grave errors into which a laboratory worker may be led by a lack of appreciation of important clinical details

Dr Gardner compares his finding of 90 per cent positive results obtained by the microscopical examination of pus from lesions of bones and joints with the 50 per cent as reported by Dr Guest and myself in a recent paper (*Journal of Hygiene*, xxv, 109) Dr Gardner will notice that Dr Guest and myself were very careful not to compare our results with those of any other observer, as such a comparison, without carefully taking into account the clinical condition of the patient and the treatment adopted, would be inaccurate

He, however, contents himself with a rough division of his cases into those with, and those without, secondary acute inflammation The finding of tubercle bacilli in pus from such morbid lesions and their number depends on various factors, and I trust I shall be pardoned if I mention a few

(*a*) Condition of patient—whether improving or getting worse

(*b*) Type of lesion —

(1) If there is acute abscess formation or an acute exacerbation of a chronic condition, tubercle bacilli can be demonstrated in 100 per cent of cases

(2) On the contrary, in a chronic case, especially if it has been frequently aspirated and is advancing towards cure the specimen is usually serous in character, and tubercle bacilli are difficult to find

(3) Again, in cases of secondary infection, especially if the discharge is profuse, tubercle bacilli are difficult to demonstrate by microscopical examination

(*c*) Method of treatment —

(1) How frequently aspiration has been performed, and at what intervals

(2) Whether any chemical—e g, magnesium sulphate solution, iodoform emulsion, &c —has been introduced into the abscess cavity on a previous occasion

(3) Heliotherapy has also been mentioned as a possible factor, but of this I have no personal experience

From the above it will be obvious that the comparison of laboratory findings, without taking into account the other important clinical factors, is bound to be unreliable

I shall now turn to another source of error Dr Gardner has evidently worked with either caseous or fluid pus If he reads the paper by Dr Guest and myself more carefully, he will note that the material examined was not classed as pus, but as "pathological material" For example one specimen was from a case of tuberculous dactylitis without abscess formation, and some of the others consisted of only granulation tissue In such conditions it is well known that the finding of tubercle bacilli in direct film preparations is much more difficult than in pus, and here again the comparison goes astray Regarding Prof Dreyer's method of counter-staining, I have compared this method with others, and in my hands, though quite useful, it showed no superiority over other reliable methods if the latter were properly applied The method of test was to make an even film on a microscope slide, and after staining with carbol fuchsin and decolorising with acid and alcohol, the slide was cut with a diamond One half was stained by one and the remaining half by the other of the two counter-stains to be tested In this way a true comparison could be made

To conclude in a less critical tone, I am glad to note that Dr Gardner has remarked on the importance of the presence of various granules in tuberculous pus He says "Tuberculous pus often, perhaps always, contains in addition to tubercle bacilli, granules of various size " With this statement I heartily concur, and would even go further and leave out "in addition to tubercle bacilli" as not being entirely essential —I am, Sir, yours faithfully,

J W EDINGTON

Sheffield University June 22nd, 1926

SURGICAL TREATMENT OF GASTRIC AND DUODENAL ULCERS

To the Editor of THE LANCET

SIR,—Recent correspondence in your journal with reference to the surgical treatment of gastric and duodenal ulcers is both timely and important I note that Mr Seton Pringle, in his able article on hour-glass stomach, has come to the conclusion that partial gastrectomy is the treatment of choice With him I am in accord entirely, and my experience goes to prove that the most satisfactory procedure is a two-stage operation Most of these patients are emaciated and for this reason I perform a posterior gastro-enterostomy first of all, anastomosing the jejunum to the proximal sac of the hour-glass The immediate effect is improvement and a gain in weight I then perform the second stage of the operation, which consists in excision of the ulcer and distal sac of the hour-glass At the second operation a most striking finding has been a diminution in size and a cessation of activity in the ulcer, both points of importance in that they render the second operation an easier and safer enterprise. I have performed this operation now on several patients and have not had a moment's anxiety in the immediate post-operative events or a single subsequent regret. Dr. Arthur F. Hurst speaks of successes over years from the operation of gastro-gastrostomy. I have performed this operation but my results have not been comparable to those obtained by a two-stage gastrectomy. I feel sure that the surgical principle underlying such treatment should be 'operate upon a quiescent ulcer rather than upon an active one,' and such a principle is achieved by a preliminary gastro-enterostomy.

We owe a debt of gratitude to Mr. R. Leonard Ley, of Great Yarmouth, for his very true remarks upon perforating gastric ulcers, and I presume he includes perforating duodenal ulcers. In an industrial city like Bradford we get a very great number to deal with in the course of a year. Out of 150 cases operated upon my mortality amounts to 8 per cent. I confine myself to closing and inverting the perforation, inserting a drain for 18 hours to the bottom of the right kidney pouch and nothing further, the operation itself taking round about 12 to 15 minutes. In only nine cases have I had to perform a subsequent gastro-enterostomy. I have been kept informed about the majority of these cases and the ultimate result has been a cure, both clinically and by X ray examination. I quite agree with Mr. Ley that gastro-enterostomy at the time of closing the perforation is both unnecessary and unjustifiable. I only wish we could hear more from general practitioners like Mr. Ley, who are doing this work and who "have to live with their patients afterwards." I for one should like to congratulate him upon a very valuable contribution to gastric surgery.—I am, Sir, yours faithfully,

BASIL HUGHES, D.S.O., F.R.C.S., &c.

Surgeon, Bradford Municipal General Hospital; Hon. Surgeon, Bradford Children's Hospital; Hon. Assist. Surgeon, Bradford Royal Infirmary.

Bradford Moor, Bradford, June 21st, 1926.

ALTERATION OF VISION DUE TO BASAL FRACTURE OF SKULL

To the Editor of THE LANCET

SIR,—A quarryman aged 24, fell, two years ago, a distance of 50 feet down a shaft coming down on his buttocks. There were signs of basal fracture, slight hæmorrhages over the mastoid processes, slight unconsciousness, some hæmorrhage from the ears. He speedily recovered. His vision had been normal before the accident. It has become slightly myopic and indistinct. I find he can read 6/6 with a minus lens 0.5, cyl. with the axes vertical both eyes. Is there any reference in literature to alterations of vision due to basal skull injury?

I am, Sir, yours faithfully,

Corris, Merioneth, June 22nd. E. C. B. IBOTSON.

THE DANGER OF AN EXTERNAL DRUG COMBINING WITH AN INTERNAL DRUG

To the Editor of THE LANCET

SIR,—On reading Dr. T. M. Allison's letter in THE LANCET of June 26th I was reminded of a very disturbing case I had several years ago. A patient came to consult me for a phlyctenular ulcer of the eye as his own medical adviser was out of town. Not knowing he was taking pot. iodide internally, I dusted the eye with calomel, and the result was a very acute inflammation due, no doubt, to the formation of iodide of mercury. I may add that though the inflammation was very severe for a few days it cleared up completely and left no permanent ill-results; in fact, recollection suggests that the phlyctenular ulcer healed up very rapidly.

I am, Sir, yours faithfully,

J. JOHNSTONE REDMOND.

Chelsea, S.W., June 28th, 1926.

YAWS AND SYPHILIS IN TROPICAL AFRICA.

MASS TREATMENT WITH BISMUTH-ARSENIC COMPOUNDS

To the Editor of THE LANCET

SIR,—In THE LANCET of Jan. 30th, 1926, Levaditi reported favourably on a new compound—namely, basic acetyloxyamino-phenylarsenate of bismuth, produced by the reaction between a soluble salt of bismuth and stovarsol. About 18 months ago it occurred to me that a mixture of bismuth sodium tartrate and soamin, para-aminophenylarsenate of sodium, might produce a better therapeutic effect than bismuth sodium tartrate by itself, the latter now placed on the market by Howard and Sons as "Sobita" which we have been using for large numbers of yaws and syphilis with good results. Over 113 000 cases of yaws and approximately 22 000 of syphilis have now been treated, and somewhat larger numbers of yaws have also been treated, with a similar preparation, in a neighbouring colony—and I estimate that there are at least nine times the total shown for yaws still to be dealt with.

I did not, at the time mentioned, realise that in mixing "soamin" and bismuth sodium tartrate a reaction might result, but since reading Levaditi's article and attempting in a crude way to produce a reaction between bismuth sodium tartrate and stovarsol, I find that on boiling together not too dilute solutions of soamin and bismuth sodium tartrate prepared separately and then brought together, a reaction resulting in a similar fine suspension takes place on heating, which suspension deposits slowly leaving a clear supernatant fluid. An hypodermic injection administered to myself of the whole preparation produced by 3 gr. each of bismuth and soamin in 2 c.cm. of water resulted in tenderness, but less swelling and discomfort than is incident upon the introduction into the tissues of the soluble bismuth salt alone. Sequent on this a case of yaws treated by me with this preparation, by intramuscular injection responded rapidly. I thereupon instructed Dr. J. G. McNaughton, our venereal diseases officer and Dr. Armstrong, attached to the Native Hospital, Dar es Salaam, to give this preparation a trial, and an extract from Dr. McNaughton's report is given below. Dr. McNaughton's clinic is a travelling clinic, and the extract is from his report for April, 1926:—

> You will observe that I have treated patients with:—yaws 1158, syphilis 538, and other diseases 625. *Yaws.*—There were about an equal number of children and adults. Several showed an almost rupial crust over the yaws, and many had tertiary manifestations in the soles of the feet and palms of the hands. The injection given was a combination of bismuth sodium tartrate (gr. 3) and soamin (gr. 2), as you recommended, in 1 c.cm. of water, administered every second day. Cases of yaws almost invariably cleared up in six days, and were so nearly healed on the fifth day (even the most severe cases) that the third injection was not given. *Syphilis.*—No primary or secondary case was seen. All were either tertiary or congenital, about 50 per cent. of each. About 10 per cent. of the tertiary cases were unable to move one or more of the limbs, on account of ankylosed joints, and I have seldom seen, even in this country, so severely ulcerated cases. These patients all received the combination of the two drugs by injection, and within 12 days—i.e., after six injections—quite 75 per cent. were completely healed. I have never seen such rapid improvement, even after bismuth injections, so that I am inclined to conclude that the addition of the soamin has accelerated the healing. In the 1696 patients who received two or more injections I saw only 10 cases of mild stomatitis. It may not be a case of post hoc propter hoc, but, in my previous experience of treatment by the bismuth salt the cases of stomatitis have been greater in number and more severe.
>
> I have seen here five *female* patients who were treated at the Sewa Hadji Hospital 18 or 24 months ago. All received injections 6, 8, or 10 in number. All these people had had extensive ulceration of the limbs. To-day they appear in perfect health. There is no sign of ulcer or sore and their general condition appears to be much better than that of their neighbours. In this connexion I noticed that after 1 or 2 injections the very severe cases of syphilis had a different look. They were brighter,

their skin and eyes seemed healthier, and I was struck by their apparently altered outlook on life

Dr Armstrong treated 15 cases and reported similar results but emphasised the fact that he did not see any stomatitis in his patients—they were, however, too few The question of treatment to us in a territory of 365,000 square miles and a scattered population of approximately ,6,000,000, a large percentage of which is afflicted with yaws, and to a lesser extent syphilis is of vital importance We cannot afford expensive drugs, nor do we think that for mass treatment with the object of reducing as rapidly as possible the enormous degree of infectivity, the immediate amelioration of the physical condition of the sufferers, and the safeguarding of the coming generation, it is necessary, or yet feasible to employ them To attempt permanent cure with the exhibition of the salvarsan group is absolutely out of the question, and, apart from expense it would be impossible to secure anything approaching regular attendance amongst an African population

In the Dutch West Indies, Dr Winckel reports the use of 400 kg of neosalvarsan, costing some £250,000, for the treatment of yaws, and his opinion is that an average of four injections were essential I have stressed these points to show that a few injections of neosalvarsan are no more valuable and do not attain any better clinical results than the use of bismuth, and that if one or other is to be used for yaws or syphilis, to achieve our local purposes relating to mass treatment, then neosalvarsan should not be used except in special cases Regarding more particularly the treatment of syphilis with bismuth sodium tartrate the reports as a whole are satisfactory but are not uniform Its resistance as compared with yaws is greater in ratio of about 4 1—namely, it requires about three to four times the quantity of bismuth for a so-called cure—that is, the entire absence of active signs and the general recovery in health of the patient Dr L W Harrison admits the great difficulty of converting a positive into a negative serum reaction One of the types of cases referred to, early secondary, requires treatment under close supervision for some three years, during which time 16 g of neosalvarsan is used costing about £8 per head, and, be it noted, with no claim to negative reaction We, on the other hand can treat approximately 500 cases of yaws or 125 of syphilis for 16*s* —the cost of staff, organisation, &c , is, of course, equal in either case

We have been using the soluble salts of bismuth in this Territory since early in 1922, shortly after Roux had stated that bismuth was of value in syphilis, before it was generally adopted by anybody, and the methods we employed at that time have resulted in about 300,000 cases of yaws being treated in Kenya, the Sudan, Zanzibar, Fiji, and this Territory I wish therefore to indicate to those interested, in view of our four years' experience and the mass of disease still remaining to be dealt with, that the quickest, and therefore the least expensive, effective measure should be taken, so far as the indigenous population of tropical Africa is concerned , otherwise we are wasting time in handling a few thousands in a futile attempt at permanent cure whilst hundreds of thousands requiring immediate relief are left untouched I hope that some of your readers, who have the welfare of the native at heart, and are in a position to test the compound produced by the interaction of bismuth sodium tartrate and soamin may give it a trial in syphilis and report as to its relative efficacy as compared with Levaditi's preparation "bistovol" The former can be prepared very simply at a cost of less than a penny a dose, whereas bistovol will probably be at a price which for us will be prohibitive Bismuth by itself is good enough for yaws, but it would appear that the compound of bismuth and soamin is much the better for syphilis—the low percentage and mild degree of stomatitis is also a decided advantage in its favour

I am, Sir, yours faithfully,
J O. SHIRCORE, M B , M R C P Edin ,
Director of Medical and Sanitary Services,
Tanganyika Territory

HOUSE OF LORDS

TUESDAY, JUNE 29TH

University of London Bill

THE University of London Bill was read a second time

HOUSE OF COMMONS

THURSDAY, JUNE 24TH

Milk for Mothers in Mining Areas

Dr SALTER asked the Minister of Health what additional provision was being made, as a consequence of the miners' dispute, for the supply of milk to nursing and expectant mothers and to young children through the county councils or local authorities —Mr NEVILLE CHAMBERLAIN replied I have no information as to any special action taken in this matter by local authorities On the question of policy, I may refer the hon Member to the reply which I gave on this subject on the 10th instant

Neurasthenic Patient's Pension

Dr SALTER asked the Minister of Pensions if he was aware that ex-stoker William Ewart Gladstone Day, No K 21,477, late Royal Navy, was granted a final award of only 15 per cent for 35 weeks in April, 1922, while still suffering from neurasthenia and deafness due to an explosion on H M S *Bulwark* in November, 1914, when he was one of only 16 survivors , and that this pension was increased to 20*s* 7*d* per week on Dec 31st, 1925, after prolonged correspondence with his department when this man's neurasthenia was assessed at 20 per cent , why the pension was reduced to 16*s* on March 2nd, 1926, when his neurasthenia was still assessed at 20 per cent and his ear condition remained unchanged , and why this pension has not been made retrospective to June 2nd, 1923, more than a year after his final award of 1 5 per cent , when he was admitted to hospital and operated on for acute mastoid disease —Major G C TRYON replied The hon Member has been misinformed The award made in 1922 to which he refers was in respect of deafness only As regards the award for neurasthenia this was originally at the rate of 30 per cent and was reduced to 20 per cent by the medical board of Jan 22nd, 1926 Mr Day did not make a claim on the Ministry in proper form in respect of neurasthenia until February, 1925, but the award in respect of that disability was made from the date of a letter on his behalf which has been accepted as constituting an earlier claim The award in respect of deafness in replacement of the award made in 1922 runs from the date of the medical examination by a Ministry doctor which definitely proved the need for the amendment of the 1922 award I can find no ground for making either award from an earlier date

Death in Bedford Prison

Mr PETHICK-LAWRENCE asked the Secretary of State for the Home Department (1) whether he was now in a position to make a statement with regard to the circumstances attending the death of Mr Reginald Russell in Bedford prison on May 23rd, and (2) what arrangements were made for removal to hospital of unconvicted prisoners who were seriously ill , what regulations existed for securing that the relatives were informed of serious illness and whether they were complied with in the present instance —Sir W JOYNSON-HICKS replied I regret to say that the report discloses errors of judgment and failure to comply with the regulations on the part of certain officials of the prison The prisoner complained of illness on April 27th and May 10th, and on May 11th took to his bed until his death on May 23rd His disease was wrongly diagnosed and he did not receive either the medical or nursing treatment which, in my opinion he should have had , nor was he removed to hospital The prisoner was suffering from kidney disease, and it may be that his condition was such that his life could not in any event have been saved, but that would not, of course, excuse in any way the mistakes and irregularities that were committed The facts of this case, deplorable as they are, do not suggest that the regulations with regard to the treatment of illness in prison are defective, but, as in all human institutions, mistakes cannot always be avoided The Secretary of State is ultimately responsible for the conduct of prison officials, and I have decided to take disciplinary measures in regard to the officers concerned I am not in a position to give my final decision in regard to these to-day, but if the hon gentleman will put down a question for to-day week, I hope to have completed my decisions

Septicœmia following Childbirth

Colonel DAY asked the Minister of Health if his attention had been drawn to the number of deaths due to puerperal septicaemia following childbirth in the Kingston area and in view of the fact that many of these cases had been connected with one nursing home in particular would he cause a full inquiry to be made as to the effectiveness of the existing county council regulations —Mr NEVILLE CHAMBERLAIN replied The answer to the first part of the question is in the affirmative As regards the second part an inquiry has already been made into these cases by one of the medical officers of my department, and her report is now under consideration

National Insurance Statistics

Sir NICHOLAS GRATTAN DOYLE asked the Minister of Health, with reference to National Health Insurance the total of the accumulated funds at Dec 31st 1925 the total payments made during the year ended Dec 31st 1925 by insured persons, employers and the State respectively , the number of insured persons male and female separately the total benefits paid during the year ended Dec 31st 1925 for sickness benefit, disablement benefit maternity benefit, medical benefit and additional benefits respectively the total amount allocated to approved societies for additional benefits the total amount retained by the State, which is regarded by the Act as surplus the number of societies which have disposable surplus for additional benefits and the number of societies in deficiency —Mr NEVILLE CHAMBERLAIN replied The particulars asked for with reference to National Health Insurance so far as available are given for England and Wales in the following statement —

		£
Total of the accumulated funds at Dec 31st 1925		113 000,000
Total payments made during the year ended Dec 31st, 1925—		
by insured persons		11 970 000
employers		12 800,000
the State		7,220,000
Number of insured persons—		
Male	9 393 000	
Female	4,350 000	
Total benefits paid during the year ended Dec 31st, 1925—		
for sickness benefit		9,335,000
disablement benefit		4,514 000
maternity benefit		1 489 000
medical benefit		8,449,000
additional benefits not included above*		761 000

*Additional benefits which take the form of increases of ordinary cash benefits (sickness, disablement, and maternity) are included in the figures for those benefits and cannot be separately stated. Payments in respect of additional benefits which do not take that form are separately shown

The total amount allocated for distribution by approved societies by way of additional benefits of every description in the year 1925 may be estimated approximately at	2 500,000
The inquiry as to the total amount retained by the State which is regarded by the Act as surplus is not understood The whole of the assets of a society consisting of— (1) Reserve values credited under Sections 66 and 69 of the Act (2) Sums standing in the investment account ' under Section 70 (3) Sums standing to the credit of the society in the National Health Insurance Fund other than in investment account ', (4) Sums invested by the society under Section 71 and (5) Cash in the hands of the society are brought into its valuation balance sheet for the purpose of the periodical valuation under Section 74 by which alone the existence of, or the amount of a surplus can be ascertained	
The number of units (i e centralised approved societies and branches of approved societies with branches) operating in England and Wales at the first valuation which had disposable surplus for additional benefits was	7,775
The number of societies and branches in deficiency was	377

The Government Actuary is preparing a report on the second valuation of the assets and liabilities of approved societies, and hopes to issue it in the autumn.

Diabetes Patient's Treatment in Prison

Mr PURCELL asked the Secretary of State for the Home Department whether his attention had been drawn to the case of Mr John Forshaw, 4, Peacock-street Salford, who after his house was raided by the police on May 14th, was taken to the Salford Town Hall police-station whether he was aware that he informed the officers that he was suffering from diabetes and asked to see a doctor; *that this request* was refused, as was also a request for the supply of blankets and that the windows might be closed, the only protection he had during the night being the coat of a man in the same cell who put his coat over Mr Forshaw who was obviously ill and whether, seeing that after conviction the next day Mr Forshaw was removed to Strangeways Hospital and died on June 9th as the result of bronchitis and pneumonia contracted in the police cell he would have a public inquiry made into this treatment given to a man prior to trial —Sir W JOYNSON-HICKS replied Forshaw was in police custody from May 14th to 17th and was not treated as an invalid and made no application to be treated as such on reception into prison on the 17th he was admitted into the prison hospital until the 20th when he was released on bail in view of his appeal to Quarter Sessions At that time there were no signs of illness other than diabetes from which he had been suffering for four years On May 21st he called on the police and expressed satisfaction with his treatment during detention both in police custody and in prison I understand that he fell ill on June 5th 16 days after his release from prison and on the facts before me no connexion is shown between his treatment while in custody and his death from bronchitis and pneumonia on June 9th

Problems of Tropical Diseases

Mr HERBERT WILLIAMS asked the Secretary of State for the Colonies whether any system existed for the exchange of knowledge on the problems of tropical diseases of man animal, and plant between his department and the corresponding departments of other countries with tropical possessions —Mr AMERY replied The Imperial Bureau of Entomology, the Imperial Bureau of Mycology and the Bureau of Hygiene and Tropical Diseases constantly receive information of the nature indicated in my hon friend's question from all parts of the Empire and foreign territories This information is summarised in the periodical monthly and quarterly reviews which are published by these bureaus and distributed to subscribers, including the Governments of the oversea dependencies I should also refer in connexion with human tropical disease to the valuable work of the health organisation of the League of Nations through which knowledge of the progress made in that direction is widely distributed between the different Governments represented in the organisation

Mr WILLIAMS Is there any link with the Dutch Government in this matter ?

Mr AMERY I think so both through the League of Nations and the use made of the excellent publication issued by their department in Java

Protection of Children in India

Mr JOHNSTON asked the Under Secretary of State for India whether any legislation had been introduced by the Government of India to protect children from maltreatment and exploitation by professional beggars agents of brothels, and if so when —Earl WINTERTON replied This matter is now in the main one for the provincial governments and legislatures to deal with Acts for the protection of children and young persons and for the trial and punishment of youthful offenders were passed in Madras Bengal and Bombay in 1920 1922, and 1924 respectively Children are protected from the agents of brothels by the Indian Penal Code which applies throughout India and the provisions of which in this respect, have recently been made more stringent

Artificial Sunlight Treatment

Captain FRASER asked the Minister of Health if he would give the names of any metropolitan boroughs in which artificial sunlight treatment had been introduced in a maternity and child welfare centre or centres and what contribution if any his department had made towards the cost of artificial sunlight equipment and or of the first year's running expenses in connexion with this treatment —Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied According to the information in the possession of my right hon friend's department, provision has been made for artificial light treatment at or in connexion with maternity and child welfare centres in the following metropolitan boroughs Bethnal Green Deptford Greenwich Hackney, Islington Kensington Poplar, St Marylebone St Pancras, Shoreditch Southwark Stepney, and Westminster In those cases in which the prior approval of my right hon friend's department was obtained to the arrangements and a contribution is desired towards the cost, the usual grant of 50 *per cent* is being paid towards the net cost of the installation and the first year's running expenses

MONDAY, JUNE 28TH.

Pit-head Baths

Mr WILFRID PALING asked the Secretary for Mines how many coal-mines in Great Britain had established pit-head baths, and how many persons such baths provided for —Colonel LANE-FOX replied At Dec 31st 1925 pit-head baths on the shower bath principle had been installed for general use at 23 coal-mines in Great Britain and were in course of installation at nine others The total number of shower bath cubicles comprised in these installations was 1729 which it may be assumed would provide accommodation for about 17,000 to 20,000 men per day These figures do not include slipper baths, plunge baths, swimming baths, or any bathing accommodation reserved for the use of officials only

Factory Legislation and Health

Sir **WILFRED SUGDEN** asked the Prime Minister if he could yet give a date when legislation upon the factory conditions of employment would be introduced , and if he would give opportunities for tested and considered practical suggestions prepared by the various industrial research associations to be included in such legislation if it be found neither to handicap nor increase cost of production, but to give healthier conditions of labour for employees —Captain **HACKING** (Under Secretary for Home Affairs) replied My right hon friend the Home Secretary has already promised to introduce the Factory Bill this session for purposes of information and consultation, and he hopes to introduce the Bill next month He will certainly give careful and sympathetic consideration to any such suggestions as are referred to in the question

Female Nurses and Insane Male Patients

Mr **CHARLES EDWARDS** asked the Minister of Health whether he was aware that at the Hellingly Asylum the East Sussex County Council employed female nurses in attendance on insane male patients , and whether, in view of the moral and physical dangers thus involved, he would take steps to prevent this practice —Mr **NEVILLE CHAMBERLAIN** replied The answer to the first part of the question is in the affirmative I am unable to accept the assumption upon which the second part of the question is based Medical superintendents who have had experience of the practice of nursing male patients by women nurses are practically unanimous in thinking that it is desirable in certain types of cases I am advised that there are certain classes of patients who can be nursed by women nurses with great advantage to the patients and without risk to the nurses I do not, therefore, propose to take action in the direction suggested by the hon Member

New Dentists Bill

Mr A **ALEXANDER** presented a Bill to amend the Dentists Act, 1921, which was read a first time

TUESDAY, JUNE 29TH

Disinfectants on Merchant Vessels

Mr **CLUSE** asked the President of the Board of Trade if he was aware that his department still approved for use on board ship chemical disinfectants which had been disapproved of for use on His Majesty's naval ships and shore establishments, and if, in view of the necessity for the prevention of the spread of infection on passenger and emigrant ships, he would consider revising the lists in consultation with the Admiralty and the Ministry of Health — Sir P **CUNLIFFE-LISTER** replied I am not aware that any of the disinfectants approved for use on board merchant vessels are unsuitable for the purpose Such disinfectants are submitted for approval and are tested chemically by the Government laboratory and bacteriologically by the Lister Institute, and if they do not come up to the required standards they are not approved The list of disinfectants so approved is continually under revision, the officers concerned having been instructed to take samples from time to time in order that a check test may be made Where such a sample is found not to conform to the required standard the name of the disinfectant in question is removed from the approved list I will, however, have the list examined as suggested by the hon Member

Venereal Disease in the Army

Mr **BASIL PETO** asked the Secretary of State for War whether the incidence of venereal disease in the Army had increased or diminished in the last three years , and what was the general view of the Army medical service as to the value of the preventive measures that had been employed—Sir L **WORTHINGTON-EVANS** replied During the last three years for which complete statistics are available, the incidence of venereal disease in the Army has decreased from 74 0 per 1000 of the strength in 1921 to 47 8 per 1000 in 1924 My medical advisers consider that this reduction is mainly due to the very effective preventive measures that have been and are still being employed I will also refer my hon friend to the information contained on pages 15–18 of the report on the health of the Army for 1924

Medical Reports and Army Pensions

Mr **HORE-BELISHA** asked the Secretary of State for War what procedure was followed in the case of men invalided from His Majesty's Army who desired to question the decision of the medical officer which deprived them of pension rights , and whether the medical officer's report, which was the basis of the complaint, was referred to and taken as evidence of the correctness of that report —Sir L **WORTHINGTON-EVANS** replied A man whose claim to disablement pension has been rejected by the Commissioners of the Royal Hospital, Chelsea, on the strength of the report of a medical board, may appeal to the Commissioners for reconsideration of his case on medical grounds and may state the grounds of his appeal The report of the medical board is considered in conjunction with the whole of the man's medical history during his Army service Any evidence which the man may adduce in his own interest is also considered and investigated by reference to his late commanding officer or other persons likely to be able to confirm his statement The opinions of the consulting physician and surgeon to the Army are obtained when necessary before a decision is given.

Puerperal Septicæmia following Childbirth

Colonel **DAY** asked the Minister of Health if, in view of the fact that further deaths had occurred from puerperal septicæmia following childbirth in the Kingston Nursing Association's home, which made a total of eight deaths from this cause during the last six months, and the criticisms made by the Kingston coroner on the conditions existing at this home, he was in a position to give further information to the House on the report that had been made on this home by one of his medical officers —Sir **KINGSLEY WOOD** replied My right hon friend has now considered this report, and regrets to say that it indicates that there has been grave laxity in the administration of this home and of the district midwifery practice associated with it He is about to address a communication to the Nursing Association dealing fully with the facts elicited by the inquiry, and he proposes to send a copy of the communication to the County Council and the Kingston Town Council My right hon. friend will be happy also to send a copy to the hon Member and to any other hon Member who desires it

The Services.

THE Orders following upon the Recommendations of the Inter-departmental Committee upon medical reform in the fighting Services were published at the end of the week They were foreshadowed in THE LANCET last week and will give the greatest satisfaction

In any case in which transfer from the old rates may involve loss the old rates will be maintained

The revised rates of pay and additional pay (but not charge pay) sanctioned by the Warrant for each corps will be subject, as from July 1st, to the deduction of 5½ per cent which was made to the old rates as from July 1st, 1924, and will further be subject to revision in respect of subsequent variation in the cost of living in the same manner and to the same extent as the rates introduced from July 1st, 1919

The amendments take effect as from July 1st, 1926

ROYAL NAVAL MEDICAL SERVICE

The exact Recommendations of the Inter-departmental Committee will be available to the public next week, including new Orders in respect of the Dental and Nursing Services

The main reforms in the Medical Service may be indicated as a result of the Recommendations The following changes in the conditions of service of medical officers, R N , will take effect from July 1st, 1926, or as soon afterwards as the necessary arrangements can be made

Surgeon Captains

The maximum number of surgeon captains will be increased from 16 to 20, two of whom will be appointed to the R N Hospital, Haslar, as professors of medicine and surgery respectively, on instructional duties connected with the general courses described below The appointment of Director of Medical Studies, Naval Medical School, R N College, Greenwich, will in future be held by a surgeon captain, and a surgeon captain will be appointed to the R N. Hospital, Malta, as second in charge

Specialists' Appointments and Allowances

Charge Pay

The number of specialist appointments will be increased from 46 to 60, and the new appointments will include specialist posts in medicine, surgery, radiology and hygiene The allowance payable to holders of specialist appointments will be increased from 2s 6d to 5s per day, as from July 1st, 1926

The grant of charge pay will be made as from July 1st 1926, on the following scale for medical officers in charge of various hospitals and sick quarters Surgeon Rear Admirals and Surgeon Captains, 10s a day Surgeon Commanders, 5s a day

Professional Courses General and Special.

Every officer below the rank of Surgeon Captain, except when he has just vacated an appointment at a home hospital or is due to take his promotion course, will be appointed, if his services can be spared, once in every four years to the R N Hospital, Haslar for a course of instruction of not less than four months' duration in clinical medicine and surgery and allied subjects At the end of the course, instead of being placed on unemployed time the officer will be appointed for duty at one of the R N hospitals at Haslar Chatham, or Plymouth unless or until he receives an appointment elsewhere

Every officer selected to hold a specialist appointment will, provided his services can be spared undergo a course of not less than six months' duration in his special subject at a civil hospital in London or other teaching centre, and will subsequently undergo a course of three months duration in that subject every four years while he is employed as a specialist

The existing senior medical officers' courses will to a large extent be superseded by these general and specialist courses which will necessitate the increase in establishments and the new arrangements will be inaugurated as soon as possible

Officers entering the service on or after July 1st, who have held resident appointments in civil hospitals less than one year before the date of entry, are eligible for ante-dating in certain circumstances which will be made public shortly

Dental Officers, R N

The rank of Surgeon Captain (D) will be introduced and the establishment of dental officers increased to 64

The Nursing Service

Detailed improvements in the Nursing Service will also be published shortly

ROYAL ARMY MEDICAL CORPS

The rates of pay of officers will be amended as follows —

Old Rates	£	s	d	*New Rates*	£	s	d
Lieut	1	2	0	Lieut	1	2	0
Capt	1	7	0	Capt	1	7	0
Capt, after six years' commissioned service	1	8	0	Capt, after eight years' commissioned service	1	10	0
Capt, after ten years' commissioned service	1	11	0	Capt, after ten years' commissioned service	1	12	6
Major	1	15	0	Major	1	17	6
Major, after 15 years' commissioned service	2	0	0	Major, after 15 years' commissioned service	2	2	6
				Major, after 18 years' commissioned service	2	5	0
				Major, after 20 years' commissioned service	2	10	0
Lieut Col	2	10	0	Lieut Col	2	17	6
Lieut-Col, after 20 years' commissioned service	2	12	6	Lieut Col after three years' service as such	3	2	6
Lieut Col after 25 years' commissioned service	2	15	0				
Colonel	3	5	0	Colonel	3	10	0
Maj-Gen	4	15	0	Maj-Gen	4	15	0
Director Gen	£2500 a year			Director Gen (plus lieut gen's allowances)	6	0	0

An officer of the Royal Army Medical Corps employed at the War Office as Assistant Director-General, Assistant Director, or Deputy-Assistant Director-General shall receive additional pay at 5s a day instead of 2s 9d as at present provided The rate of additional pay for officers of the Royal Army Medical Corps appointed to act as specialists shall be increased to 5s a day for all subjects

An officer commissioned after holding a resident appointment of not less than one year in a civil hospital may be granted an antedate not exceeding one year in respect of the period spent in such an appointment provided that the interval between the termination of the hospital appointment and the date of entry into the service shall not ordinarily exceed six months This antedate will count as commissioned service for the purpose of increments of pay, promotion, retirement, retired pay, and retiring gratuities An officer shall be eligible to retire with a gratuity of £1000 after seven years' service instead of after eight and a half years', and an officer who, after three years' service as a major is eligible to retire with a gratuity of £1800 or after six years' service as a major with a gratuity of £2500, shall be eligible to retire with £2800 in lieu of £1800 and £3500 in lieu of £2500

An officer serving as a medical officer, R A M C, on Sept 13th 1919, shall be eligible on retirement as a major after 20 years' service for retired pay at a daily rate of £1 if more favourable to him than the rate assessed under the ordinary scale for medical officers An officer who has retired as a major since Sept 13th, 1919, after completing 20 years' service will be entitled to benefit under this provision with effect from the date of retirement

ROYAL AIR FORCE MEDICAL SERVICE

It has been announced from the Air Ministry that increases of pay have been granted in all ranks above flight lieutenant, promotion to which rank occurs after two years' satisfactory service In this Service entry does not commit the officer to permanency, permanent commissions being granted by selection from officers holding a short service commission, freedom being thus allowed to the individual and to the authority. There has been an increase in the gratuities granted to short service officers passing to the Reserve both after three years' and after five years' service Higher allowances are made to married officers and the retiring allowances to permanent officers have been increased Larger opportunities are also being given to permanent officers to pursue professional study while the tenure of house appointments in civil hospitals entitles the officer to antedating for promotion purposes

ROYAL ARMY DENTAL CORPS

The rates of pay of officers will be amended as follows —

Old Rates	£	s	d	*New Rates*	£	s	d
Lieut	1	0	0	Lieut	1	0	0
Capt	1	5	0	Capt	1	5	0
Capt., after six years' commissioned service	1	6	6	Capt after eight years' commissioned service	1	8	0
Capt, after ten years' commissioned service	1	8	6	Capt after ten years' commissioned service	1	10	0
Major	1	13	0	Major	1	15	0
Major after 15 years' commissioned service	1	18	0	Major after 15 years' commissioned service	2	0	0
				Major, after 18 years' commissioned service	2	2	6
				Major, after 20 years' commissioned service	2	7	6
Lieut-Col	2	7	6	Lieut Col	2	15	0
Lieut Col, after 20 years' commissioned service	2	10	0	Lieut Col, after three years' service as such	3	0	0
Lieut Col, after 25 years' commissioned service	2	12	6				
				Colonel	3	7	6

A captain in the Army Dental Corps will be eligible for promotion to the rank of major after 12 years' commissioned service in the corps provided that he has qualified in such manner as may be prescribed by the Army Council The officer appointed to the charge of the Dental Laboratories, Aldershot, will do not include slipper baths, plunge baths, swimming baths, or any bathing accommodation reserved for the use of officials only

Factory Legislation and Health

SIR WILFRED SUGDEN asked the Prime Minister if he could yet give a date when legislation upon the factory conditions of employment would be introduced, and if he would give opportunities for tested and considered practical suggestions prepared by the various industrial research associations to be included in such legislation if it be found neither to handicap nor increase cost of production, but to give healthier conditions of labour for employees —Captain HACKING (Under Secretary for Home Affairs) replied My right hon friend the Home Secretary has already promised to introduce the Factory Bill this session for purposes of information and consultation and he hopes to introduce the Bill next month He will certainly give careful and sympathetic consideration to any such suggestions as are referred to in the question

Female Nurses and Insane Male Patients

Mr CHARLES EDWARDS asked the Minister of Health whether he was aware that at the Hellingly Asylum the East Sussex County Council employed female nurses in attendance on insane male patients, and whether, in view of the moral and physical dangers thus involved, he would take steps to prevent this practice —Mr NEVILLE CHAMBERLAIN replied The answer to the first part of the question is in the affirmative I am unable to accept the assumption upon which the second part of the question is based Medical superintendents who have had experience of the practice of nursing male patients by women nurses are practically unanimous in thinking that it is desirable in certain types of cases I am advised that there are certain classes of patients who can be nursed by women nurses with great advantage to the patients and without risk to the nurses I do not, therefore, propose to take action in the direction suggested by the hon Member

New Dentists Bill

Mr A ALEXANDER presented a Bill to amend the Dentists Act, 1921, which was read a first time

TUESDAY, JUNE 29TH

Disinfectants on Merchant Vessels

Mr CLUSE asked the President of the Board of Trade if he was aware that his department still approved for use on board ship chemical disinfectants which had been disapproved of for use on His Majesty's naval ships and shore establishments, and if, in view of the necessity for the prevention of the spread of infection on passenger and emigrant ships, he would consider revising the lists in consultation with the Admiralty and the Ministry of Health —Sir P CUNLIFFE-LISTER replied I am not aware that any of the disinfectants approved for use on board merchant vessels are unsuitable for the purpose Such disinfectants are submitted for approval and are tested chemically by the Government laboratory and bacteriologically by the Lister Institute, and if they do not come up to the required standards they are not approved The list of disinfectants so approved is continually under revision, the officers concerned having been instructed to take samples from time to time in order that a check test may be made Where such a sample is found not to conform to the required standard the name of the disinfectant in question is removed from the approved list I will, however, have the list examined as suggested by the hon Member

Venereal Disease in the Army

Mr BASIL PETO asked the Secretary of State for War whether the incidence of venereal disease in the Army had increased or diminished in the last three years, and what was the general view of the Army medical service as to the value of the preventive measures that had been employed—Sir L WORTHINGTON-EVANS replied During the last three years for which complete statistics are available, the incidence of venereal disease in the Army has decreased from 71 0 per 1000 of the strength in 1921 to 47 8 per 1000 in 1924 My medical advisers consider that this reduction is mainly due to the very effective preventive measures that have been and are still being employed I will also refer my hon friend to the information contained on pages 15–18 of the report on the health of the Army for 1924

Medical Reports and Army Pensions

Mr HORE-BELISHA asked the Secretary of State for War what procedure was followed in the case of men invalided from His Majesty's Army who desired to question the decision of the medical officer which deprived them of pension rights, and whether the medical officer's report, which was the basis of the complaint, was referred to and taken as evidence of the correctness of that report —Sir L WORTHINGTON-EVANS replied A man whose claim to disablement pension has been rejected by the Commissioners of the Royal Hospital, Chelsea, on the strength of the report of a medical board, may appeal to the Commissioners for reconsideration of his case on medical grounds and may state the grounds of his appeal The report of the medical board is considered in conjunction with the whole of the man's medical history during his Army service Any evidence which the man may adduce in his own interest is also considered and investigated by reference to his late commanding officer or other persons likely to be able to confirm his statement The opinions of the consulting physician and surgeon to the Army are obtained when necessary before a decision is given

Puerperal Septicæmia following Childbirth

Colonel DAY asked the Minister of Health if, in view of the fact that further deaths had occurred from puerperal septicæmia following childbirth in the Kingston Nursing Association's home, which made a total of eight deaths from this cause during the last six months, and the criticisms made by the Kingston coroner on the conditions existing at this home, he was in a position to give further information to the House on the report that had been made on this home by one of his medical officers —Sir KINGSLEY WOOD replied My right hon friend has now considered this report, and regrets to say that it indicates that there has been grave laxity in the administration of this home and of the district midwifery practice associated with it He is about to address a communication to the Nursing Association dealing fully with the facts elicited by the inquiry, and he proposes to send a copy of the communication to the County Council and the Kingston Town Council My right hon friend will be happy also to send a copy to the hon Member and to any other hon Member who desires it

The Services.

THE Orders following upon the Recommendations of the Inter-departmental Committee upon medical reform in the fighting Services were published at the end of the week They were foreshadowed in THE LANCET last week and will give the greatest satisfaction

In any case in which transfer from the old rates may involve loss the old rates will be maintained

The revised rates of pay and additional pay (but not charge pay) sanctioned by the Warrant for each corps will be subject, as from July 1st, to the deduction of 5½ per cent which was made to the old rates as from July 1st, 1924, and will further be subject to revision in respect of subsequent variation in the cost of living in the same manner and to the same extent as the rates introduced from July 1st, 1919

The amendments take effect as from July 1st, 1926

ROYAL NAVAL MEDICAL SERVICE

The exact Recommendations of the Inter-departmental Committee will be available to the public next week, including new Orders in respect of the Dental and Nursing Services

The main reforms in the Medical Service may be indicated as a result of the Recommendations The following changes in the conditions of service of medical officers, R N, will take effect from July 1st, 1926, or as soon afterwards as the necessary arrangements can be made

Surgeon Captains

The maximum number of surgeon captains will be increased from 16 to 20, two of whom will be appointed to the R N Hospital, Haslar, as professors of medicine and surgery respectively, on instructional duties connected with the general courses described below The appointment of Director of Medical Studies, Naval Medical School, R N College, Greenwich, will in future be held by a surgeon captain, and a surgeon captain will be appointed to the R N Hospital, Malta, as second in charge

Specialists' Appointments and Allowances Charge Pay

The number of specialist appointments will be increased from 46 to 60, and the new appointments will include specialist posts in medicine, surgery,

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning

Monday, July 5th —5 P M., General Meeting of the Members

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASE, 11, Chandos-street, Cavendish square, W
Friday, July 9th —8 30 P M , Fifth Annual General Meeting

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole street, London, W
Monday July 5th, to Saturday, July 10th —Special demonstration in clinical surgery by Mr Cairns Forsyth at the Royal Waterloo Hospital on Monday at 2 30 P.M. Special demonstration in clinical ophthalmology by Mr MacCallan on Thursday at 3 P M at the Royal Eye Hospital These demonstrations are open to all members of the medical profession, without fee — Hospital for Diseases of the Skin, Blackfriars S E Afternoon course in Dermatology consisting of instruction in the Out Patient Department Tuesday, selected cases by Mr Haldin-Davis

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N
Monday July 5th —10 A.M., Surgical Out-patients Mr W E. Tanner 10 30 A.M., Gynæcological Operations Mr A. E Giles Throat, Nose and Ear Operations Mr W Ibbotson 2 P.M., Medical, Surgical, and Gynæcological Clinics Operations 6 30 P M., Venereal Department Mr R Coyte
Tuesday —2 P M , Medical Surgical, Throat Nose and Ear Clinics, Operations 3 P M , Dr J K C Laing Demonstration of cases illustrating Types of Mental Disease at the Colney Hatch Mental Hospital, New Southgate, N
Wednesday —10 30 A M Surgical Operations Mr E. Gillespie 2 P.M , Medical, Eye, and Skin Clinics Operations 3 P.M Mr T H C Benians Pathological Demonstration of Tumours of the Breast 5 30 P M , Venereal Department
Thursday —10 30 A.M , Dental Out-patients Mr E S Pierrepont 2 P M Medical, Surgical, and Throat, Nose and Ear Clinics, Operations 5 P.M., Operations
Friday —10 30 A.M. Eye Operations Mr N Fleming 2 P M , Surgical Medical and Children Clinics Operations 3 P M., Gynæcological Clinic. 6 30 P.M Venereal Department Dr F L Provis

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL. Gray's Inn road, W C
Friday, July 9th.—3 P M. Mr Watkyn-Thomas Indications for the Radical Mastoid Operation.

CANCER HOSPITAL, Fulham road, S W
Friday, July 9th —4 30 P M., Sir Thomas Horder · The Cachexia of Malignant Disease and its Treatment

LONDON SCHOOL OF DERMATOLOGY, 49, Leicester square, W C
Tuesday, July 6th.—5 P.M., Dr Haldin-Davis Drug Eruptions
Thursday —5 P.M., Dr J T. Ingram Pathological Demonstration.

Appointments.

Benson, Elizabeth E., M B , Ch B Brist , has been appointed Medical Officer to the Gloucester Board of Guardians

Comber Violet, M.B Lond Resident Medical Officer at Willesden Municipal Hospital

Dowling, Eileen M.B Ch B Liverp , in charge of the Maternity and Child Welfare work at West Ham

Hearn, L W M.B , B S Durh., Resident Medical Officer Hull Sanatorium

Lewis, Graham, M S Lond F R C S Eng , a Consulting Gynæcologist to the Birmingham General Dispensary and also Honorary Consulting Gynæcologist to the West Bromwich and District Hospital

Tranmere Infirmary Johnson W M.D Liverp Visiting Physician Hatton J and Roberts, J T C , Junior Resident Assistant Medical Officers

Certifying Surgeons under the Factory and Workshop Acts Hall, J S , M B Ch B Glasg (Rothesay), Ligertwood, C E. M B , Ch B Manch (Wiveliscombe)

Vacancies.

Births, Marriages, and Deaths.

BIRTHS

Anderson —On June 21st, at " Seacroft " Gorleston, the wife of Dr A. S K Anderson, D S O M C , of twin sons

Garratt —On June 26th, at Myrtle House, Dunstable-road. Luton, Beds, the wife of Frank Garratt, M.R.C S , L R.C P , of a son.

Stanley —On June 22nd, at rue des Belles Feuilles, Paris the wife of E Gerald Stanley, M.D , M.S , F R.C S , of a daughter

Wilson —On June 22nd, at Birmingham, Gwen, the wife of R K. Wilson, F R.C S Edin , of a son.

MARRIAGES

Buckley—King —On June 23rd, at St Andrew's Church, Ashley-place Captain Charles Dudley Maybury Buckley M C , R.A.M C , and Shelagh Patricia, daughter of the late James Claude King and Mrs Claude King, and niece of Colonel C W Mainprise, D S O , A.M.S.

Cutler—Hussey-Walsh.— On June 24th, at St Mary's, Cadogan gardens, Lennard Cutler, M.R.C S , L.R C P , to Maud Marie, only daughter of the late Colonel William Hussey-Walsh, Royal Welch Fusiliers, and Mrs Hussey-Walsh, Ennismore gardens, S W

Lupton—Tuckey —On June 22nd, in Ripon Cathedral Charles Athelstane Lupton, M.C F R C S , to Esther Isabel only daughter of Canon and Mrs Tuckey, of Littlethorpe Manor, Ripon.

Murray Bligh—Underwood —On June 24th, at St Francis Xavier's Church Liverpool John Murray Bligh M.D , M.R C P , of 74, Rodney-street, Liverpool, to Emily Elizabeth Underwood

Panton—Heath —On June 24th, at St Mary's Church Ashton-on-Mersey, by the Rev R. Main assisted by the Rev D E. Sturt, John Allison Panton M.D , Ch.M., F R.C S Eng and Edin , only son of the late Dr J E. Panton and Mrs W A. Bridson, of Bolton, to Kathleen Amy, only daughter of Mr and Mrs Robert Heath, of Vernon Lodge, Brooklands, Cheshire

DEATHS.

Cameron —On June 20th, suddenly, at ' Dawnie " Ariadne-road Worthing, Allan Gordon Russell Cameron, M.B , D.P H

Clarke.—On June 22nd, in Paris Robert Henry Clarke, M.B , M R.C S , of Duppas Hill-road Croydon, aged 73

Crouch —On June 25th at Harley-place Clifton, Bristol, Charles Percival Crouch, F R C S aged 65

Crowther John Woodwood, M.R C S L S A. late Hon. Consulting Surgeon to West Bromwich and District Hospital, on June 11th, at his residence, Marloes Russell - road, Lee on Solent

Inkster.—On June 23rd, at Bourton Hall Totnes and formerly of Broomhill Lodge Sheffield, Samuel Macaulay Inkster M D C M Edin aged 77

Lane.—On June 21st at Carlton-avenue Kenton Harrow, Frederick Herbert Lane, M R.C S , late of Brixton Hill S W and Burford, Oxon

Maclay — At Bamburgh suddenly on June 26th Neil Maclay M B , C M of 2 Fenham terrace Newcastle-on Tyne aged 53 years, dearly beloved husband of Mary Maclay

Pisani —On June 22nd in London Lieut -Colonel Lionel John Pisani, F I C S , I M.S , retd aged 64

N B —A fee of 7s 6d is charged for the insertion of Notices of Births Marriages, and Deaths

The Secretary of State for the Colonies has appointed Dr A T Stanton to be his chief medical adviser, taking up his duties in August next Since 1921 Dr Stanton has held the post of Director of Government Laboratories in the Federated Malay States

Rates on Hospitals —The recent revaluation of property at Newcastle-upon-Tyne has resulted in heavy increases in the assessments of the hospitals The old assessment of the Royal Infirmary was between £120 and £130, it has now been increased about twenty-fold The assessment of the Eye Infirmary has been increased from £17 to £200

Venerable Order of the Hospital of St John of Jerusalem —The King has sanctioned the following promotions in and appointments to the Venerable Order of the Hospital of St John of Jerusalem *As Knights of Grace* Captain Charles Arthur Coventon, R A M C (T A), Dr Henry Howorth Bashford, and Lieut -Colonel John Calderwood Strathearn *As Esquires* Dr Meredith Young, Dr William Richard Bates, Major Rupert Briercliffe, Major James Abbey Henderson R A M C (T F), Dr Robert Ashleigh Glegg Colonel James John Pratt, and Major James Smith Mather, R A M C (T)

St Thomas's Cornwall Babies' Hostel —This dietetic hostel, situated in the midst of the St Thomas's Hospital maternity district, has been open in its present form only 18 months, but the annual report shows that it is doing excellent work In addition to saving the lives of babies suffering from gastro-intestinal disturbance, teaching mothers the proper care of their infants, and testing breast-feeding the hostel is of value as a training centre The medical officer, Dr K J Hamilton points out that the comparatively small number of babies enables the student to study each case in detail

The late Dr R J Colenso —Dr Robert John Colenso, who died on June 2nd was a noted figure amongst the practitioners of South Kensington, where he had worked for 35 years Born in Norfolk in 1850, he was the son of the Rt Rev J W Colenso, formerly Bishop of Natal, and was educated in Kensington and at Oxford University After medical study at St Bartholomew's Hospital he became M R C S in 1878 and proceeded to the M D degree at Oxford in 1899 For a time he served as resident medical officer of the Windsor Royal Infirmary, but on being gazetted surgeon to the Natal Royal Rifles, went out to South Africa where he engaged in practice and became proficient in the Zulu language On his return to England he showed great interest in anatomy and published a number of valuable papers on the subject He also contributed to medical journals and wrote natural history sketches on South African animals, which showed his love of sport and the open air He was a skilful angler and a good shot, and keenly advocated the outdoor life which had made him robust and alert His presence and help will be missed by many

London (R F H) School of Medicine for Women —The presentation of prizes and certificates was made by Sir John Ferguson at the London School of Medicine for Women on June 25th, when Lady Barrett presided over a meeting of supporters, including Lord Riddell, president of the hospital, Dr Scharlieb, Mr J A Gardner, Miss Angus, and Mr Willmott Evans In opening the proceedings, Lady Barrett referred to the great loss which the school had sustained by the death of its late dean, Dame Louisa Aldrich-Blake The working year had been a most successful one and of the 25 distinctions granted to hospital schools by the University of London eight have been won by the London School of Medicine for Women It was said that the Battle of Waterloo was won on the playing fields of Eton, but Lady Barrett was quite sure that the battle of health with disease was also won on playing fields and she congratulated the school on having acquired a sports grounds of 6½ acres This was in process of development and towards the cost the Council had given £3000, while the students and their friends had contributed more than £2000, but £1100 was still required Other features of the year, she added were the progress of the children's ward, the opening up of a light treatment department, and the extension of the maternity department, due in great measure to the munificence of Lord Riddell The principal prize-winners were The Dean's Medal for Skill in Clinical Medicine K M Bowman-Manifold Gant Medal in Surgery and the Richardson-Kuhlmann Prize in Senior Subjects E Clarke Richardson-Kuhlmann Prize in Obstetrics E Clarke and F D Fox (divided) Dorothy Chick Gift M Low Directors' Medal in Gynæcology, presented by Prof A L McIlroy J Hoare

Guy's Hospital —On Thursday July 8th at 3 P M, Mr F D Acland, chairman of the Dental Board of the United Kingdom, will open the extension of the Dental School

Chelsea Hospital for Women —The convalescent home at St Leonards belonging to this hospital is about to be reopened after extensive alteration and improvements Much sanitary work was needed, and among other additions four more beds have been provided and the domestic accommodation considerably enlarged

Society of Medical Officers of Health —The annual meeting of the Maternity and Child Welfare Group will be held at Caxton Hall, Westminster, on Tuesday, July 6th, at 5 30 P M, when Mr George Waugh will open a discussion on Tonsils and Adenoids Amongst other speakers will be Dr R C Clarke and Dr Harold Waller, and the meeting will be open to members of the medical profession After the meeting, at 7 30 P M, there will be a dinner at the Florence Restaurant, Rupert-street, W Particulars may be had from the hon secretary, Dr M Emslie, 1, Upper Montague-street, London, W C 1

Wigan Infirmary —The board of management in its annual report states that last year, despite the industrial depression, the miners and the workers in the various industries in the Wigan mining area by means of their scheme of systematic weekly hospital contributions raised £16,541 towards the maintenance of the infirmary, a decrease of only £791 in the previous year's record The deficit was partly compensated for by the bequest of £10,000 by the late Miss Ann Dawber, of Wigan and Parbold, the interest on which will help to make up for the diminished weekly contributions

The late Dr A G R Cameron —Dr Allan Gordon Russell Cameron, who died at Worthing on June 19th at the age of 58, was the son of Mr D C Cameron, of Wakenaam, British Guiana He studied at University College and at St Mary's Hospital, London, and qualified in 1891, graduating in medicine at Durham a year later After holding an appointment in Wales he was for a time medical officer to the Metropolitan Asylums Board, after which he went to India, where he received the thanks of the Government for his work in connexion with plague In 1905 Dr Cameron was appointed county medical officer to the West Sussex County Council and settled in Worthing He was an energetic worker and did a great deal for his large area In 1913 he went to Durham as deputy medical officer for the county, and there remained for ten years For the last few years he had been living at Worthing

Institute of Hygiene —A reception was held by Sir Thomas Carey Evans at the Institute on June 29th to meet Dr Charles James Hastings, medical officer of health for Toronto Dr Hastings, who is past-president of both the American and Canadian Public Health Associations, gave an address in which he said that the first duty of a statesman is the care of the public health This must begin, he said, where eugenics leaves off—namely, with the germ plasm—and it must not be forgotten that the infant is nine months old when it is born After antenatal care the next link in the chain is the care of the new-born child, then of the pre-school child, then there must be medical examination of every child on entering school, medical, dental, and nursing care of every child at school, and a further examination of every child on leaving school It was regrettable that so many health departments had so long neglected those engaged in industry Dr Hastings went on to describe the reforms which had been made in Toronto and discussed infected milk as a danger to children and others Municipalities which do not efficiently safeguard water- and milk-supplies are, he considers, guilty of criminal negligence

The late Dr S G Mostyn —We regret to learn that Dr Sydney Gwenffrwd Mostyn was killed in a motoring accident on June 21st whilst on holiday in Scotland He was 59 years of age and had been medical officer of health for Darlington since 1911 He received his medical education at St Bartholomew's Hospital and from the time of his qualification in 1902 devoted himself to public health work As assistant in the County Health Department of the West Riding he gained wide practical experience and for a time he was responsible for the Public Health Laboratory He became familiar with hospital administration whilst resident medical officer of the Newcastle Infectious Diseases Hospital, and on appointment as medical officer of health for South Shields brought to his work a sound knowledge of his profession, which bore fruit both there and in Darlington Dr Mostyn was a graduate in arts and medicine of the University of Oxford He leaves a widow

A Lecture
ON
NON-TUBERCULOUS INFECTIONS OF THE KIDNEY.

Delivered at St Bartholomew's Hospital on June 2nd and June 4th

By HUGH CABOT, C.M.G., M.D., LL.D.,
PROFESSOR OF SURGERY, UNIVERSITY OF MICHIGAN.

PART I

CORTICAL INFECTION.

I WANT to essay the difficult task of unravelling the complicated classification of non-tuberculous infections of the kidney. I am excluding tuberculosis because it behaves differently, and may be regarded as a separate type of infection.

In considering this non-tuberculous group it is wise to exclude the adventitious causes of infection, and start with the proposition that the kidney was normal up to the time that the accident occurred. This makes it unnecessary to consider infections which depend on extraneous causes, such as stone in the kidney or obstruction of the ureter or in the lower urinary tract.

Dealing with a group in which the kidney is deemed to have been normal before it became infected, we can divide the infections into two distinct types, recognising that they overlap and that mixtures may occur. Until recent times it has been the custom to group cases according to the infecting organism but the more I see of them the more doubtful I am that that is a sound classification. We can group them instead according to the pathological findings, and point out that certain types of infecting organisms are most likely to produce particular lesions; on this plan they may be divided into cases which have a cortical lesion and those in which the pelvis of the kidney is chiefly affected. To-day I shall devote my main attention to the cortical type—those infections caused by pus-producing organisms the staphylococci and streptococci. Most commonly *Staphylococcus aureus* is responsible; less commonly *Staphylococcus albus* and *Staphylococcus citreus* more rarely still.

Incidence is less important in this group than in the subsequent group, and there is no very important distinction between the sexes in regard to the frequency of this infection. My experience has led me to believe that it is relatively uncommon in childhood, though why this is so I am not clear. It is ordinarily seen in adult life rarely in late adult life.

There is wide agreement that in this type the infection is practically always blood-borne. It is a hæmatogenous infection which has been regarded—erroneously, I think—as the only common type of hæmatogenous infection. It is commonly associated with lesions on the surface of the body, usually of the carbuncle form; but also more frequently than we suspect with sore-throat—staphylococcic rather than streptococcic. It may also be associated with acute osteomyelitis. This is a rarer but not perhaps so uncommon as we imagine; the lesion is not severe, and it may be masked by other symptoms. It is generally possible to demonstrate some lesion to which the kidney trouble is secondary. The superficial lesion may have nearly or even completely, healed before the kidney process has so developed as to be evident. Hence the need for going carefully into the history.

PATHOLOGICAL FINDINGS

The characteristic lesion here is the subcortical abscess which sometimes pushes up the capsule of the kidney so as to make itself quite evident. In the milder cases it is probable that there are only a few of these lesions. I say "probable" because the lesions are very rarely seen either at operation or at post-mortem. The more developed of the cases show the cortex of the kidney studded with small yellowish dots, and on section these areas will be found extending down into the organ for a considerable distance, though chiefly confined to the cortical zone. In the most severe stage there is a massive breaking down of the kidney, a lesion which, 20 years ago, was described as carbuncle of the kidney, partly because in some ways it resembles carbuncle and partly because it was thought to be almost universally associated with a carbuncle of the skin. These infections may overwhelm the kidney, so that in 48 hours, or even less, there is practically complete necrosis. I remember two or three cases with this type of lesion in which, on the attempt being made to remove the kidney, the organ practically came away in the hand; it was wholly necrotic and there was complete thrombosis of the blood-supply. Lesions occur which are typically wedge-shaped and these have been regarded as embolic in origin, it being assumed that they are due to the plugging of a large terminal vessel with a septic embolus. I do not know that such an assumption is necessary because with a relatively localised lesion in the neighbourhood of the cortex the process will extend so as to produce, at a later date, thrombosis of main vessels secondary to the earlier lesion.

The clearly-cut types are generally fairly evident clinically, and it is therefore more important for us to consider the milder cases, in which the diagnosis may be in doubt owing to insufficient evidence. There may be only a relatively small number of abscesses in the kidney, but although most of them resolve naturally, they are the common precursor of true perinephritic abscess. I say "true" because I want to localise my field. In literature the conditions described as perinephritic abscess are generally subdivided into those in which the abscess is secondary to such conditions as stone or tuberculous pyonephrosis and a group which should not be called perinephritic as they are simply lumbar abscesses, often due to an infection of bone. This group is not the one to which I want to call your attention to-day, because these cases are properly regarded as secondary to some other lesion, the other lesion being the real one which should attract our attention and treatment.

The type of infection of most importance is that in which the onset is insidious which develops slowly and in which the diagnosis may be obscure for a long time. I believe these cases are directly traceable to infections of the kidney by pus-producing organisms, in which the lesion affects the kidney lightly and in which the kidney is able to look after itself. One or more of the lesions breaks through the true capsule and gets into the perinephric fat where it can develop without causing symptoms. If in such cases the patient is seen relatively early in the disease there can be found in otherwise normal urine staphylococci, (commonly *Staphylococcus aureus*), in numbers which transcend the possibility of simple contamination. These staphylococci are present only for a relatively short time.

SIGNS AND SYMPTOMS

Clinically we may divide this type of infection into acute subacute, and what I would call the chronic except that I prefer to call it the perinephritic type, which is so mild that if it causes any lesion at all it produces it in the perinephritic space. To the acute might be added a per-acute group, in which there is an overwhelming infection, coming on suddenly, and in which the clinical picture is often that of an abdominal infection. Practically all the cases of this that I have seen have been regarded as cases of acute abdominal emergency, and the idea has often been that there was an acute hæmorrhagic pancreatitis. The onset is sudden and the effect on the patient very severe; there is a rapid weak pulse, and a high temperature, and the condition borders on collapse. In some of the cases the lesion is confined to one kidney and its removal, even if the patient is in extremis, will result in a recovery which is prompt and complete. But it is an unusual condition; one might go for years without seeing it even in a large

Notes, Comments, and Abstracts.

THE HEALTH, PENSIONS, AND UNEMPLOYMENT ACTS.

DOCTORS AND DENTISTS AS EMPLOYERS

THE Widows', Orphans', and Old Age Contributory Pensions Act, 1925, which came into operation on Jan. 4th, 1926, applies to all persons who are subject to compulsory health insurance; combined health insurance and pension contributions are, therefore, payable for all such persons in the service of medical and dental practitioners. As there appears to be a certain amount of misapprehension about the liability of the practitioner as employer under the National Health Insurance, Contributory Pensions and Unemployment Insurance Acts the Ministry of Health has issued a statement explaining the position.

Health and Pensions Insurance

In general, insurance under the National Health Insurance and Contributory Pensions Acts is compulsory for every person who is employed under a contract of service, if the employment is remunerated at a rate not exceeding in value £250 a year, or where the employment is by way of manual labour, irrespective of the rate of remuneration. A person employed as an apprentice or pupil is similarly required to be insured if he receives wages or other money payment (whether in the form of the return of apprenticeship premium or otherwise) in respect of his services. Thus among insurable employees may be included nurses, dental mechanics and apprentices, secretaries, reception clerks, domestic servants, hall porters, and chauffeurs.

In arriving at the rate of remuneration of persons not manually employed, account should be taken of the value to the employee (e.g., a resident secretary or nurse) of any emoluments in kind such as board and lodging provided at the employer's expense. In the case of part-time employment the equivalent remuneration for normal full-time employment should be taken.

The question whether an employment is or is not by way of manual labour arises not infrequently in the case of dental mechanics and chauffeurs, where the rate of remuneration is in excess of £250 a year. A dental mechanic employed solely in a dental workroom in making artificial teeth, crowns, &c., is regarded as employed by way of manual labour. A dentist's assistant, however, who is engaged mainly in the ordinary duties of a qualified dentist (such as attendance on patients and dental surgery), or whose main duties consist of the supervision of other employees, is regarded as employed otherwise than by way of manual labour. In cases where an assistant may be engaged partly in the mechanical work of making artificial teeth, and partly in non-manual duties as mentioned above, regard must be paid to the main and substantial nature of his duties. In any case of doubt, whether employment is or is not by way of manual labour, it is desirable that reference should be made to the Ministry of Health for a ruling.

A chauffeur who is required to clean a car and to effect running repairs, in addition to driving, is normally regarded as employed by way of manual labour, and is, therefore, compulsorily insurable irrespective of the rate of his remuneration.

Unemployment Insurance

Except as stated below, contributions under the Unemployment Insurance Acts have to be paid in respect of any person whose employment falls within the scope of compulsory health and pensions insurance. As regards persons employed by members of the professions, there are three main classes in which liability to unemployment insurance does not coincide with liability to insurance under the Health Insurance and Pensions Acts—viz., employment as a female professional nurse for the sick, employment in domestic service, and employment in agriculture, including horticulture.

Female nurses have been excepted from unemployment insurance since July, 1922, but this exception does not extend to dispensers, secretaries, or persons employed by doctors or dentists merely to receive patients, make appointments, and answer telephone messages, even though such persons may have undergone training as professional nurses.

Employment in domestic service is excepted from liability to insurance only where the employed person is not employed in a trade or business carried on for the purposes of gain. It has been held by Mr. Justice Roche in the High Court that a doctor is carrying on a business for the purpose of gain within the meaning of the Act, and domestic servants employed in that business are, therefore, required to be insured. The judge decided that a chauffeur employed primarily to drive a doctor on his rounds, and a domestic servant employed by a doctor in a nursing home carried on by him in addition to his practice, were employed in the business of their respective employers. These decisions are held to cover in principle chauffeurs employed to drive or accompany doctors on their rounds; servants employed to attend upon the patients or staff in a nursing home; and servants employed at the surgeries of doctors or dentists to admit patients, make appointments, or do other work in connexion with the employer's professional requirements.

Servants employed in doctors' or dentists' private residences solely in connexion with their employer's personal needs, and servants whose duties in connexion with their employers' business are confined to cleaning the surgery and admitting occasional patients, are not regarded as employed in the business, and are not, therefore, required to be insured against unemployment.

Employment in agriculture which concerns gardeners, whether regular or jobbing, is totally excepted from unemployment insurance.

MEDICAL WOMEN'S FEDERATION

THE annual general meeting was held on June 17th, under the chairmanship of Miss Frances Ivens, the retiring President. It was agreed that the sum of £100 from the accumulated balance of the Federation be given to the Dame Louisa Aldrich-Blake Memorial Fund and be definitely earmarked as a contribution to the proposed Scholarship Fund. The business meetings of the Council took place at the London School of Medicine for Women. The first business was the election of the officers. Dr. Christine M. Murrell was elected President, Dr. Ellen B. Orr and Dr. Clara Stewart Vice-Presidents, and Dr. Jane Walker, J.P., honorary treasurer. These, together with Miss Frances Ivens, past-President, Lady Berry, honorary secretary, and Miss Mabel Ramsay elected from the Council, compose the Executive Committee for the coming year. Reports of the various standing committees and sub-committees of the Federation were received and discussed. The report of the Aviation Subcommittee evoked much interest. The subcommittee, which consisted of members representing medicine, surgery, physiology, neurology, and gynæcology, recorded the opinion that the various qualities which produce the "flying aptitude" are found in women as well as men. They specially considered the question of menstruation and pregnancy in relation to women's fitness for flying and for receiving aviation certificates. In this connexion they examined the results of recent research into the effect of menstruation on the various processes of the body, especially researches carried on at the London School of Medicine for Women under the direction of Prof. W. Cullis, which showed that there was no change during menstruation in basal metabolism, pulse-rate, or blood pressure, also that the cost to the organism of a certain amount of work, and the recovery rate from work, was the same both during menstruation and the inter-menstrual time. They arrived at the conclusion that normal menstruation was no bar to flying, and considered that the searching and repeated medical examinations already in force in regard to those holding certificates would be sufficient to prevent persons in an unfit condition from undertaking flights. It was reported to the meeting that the International Commission on Air Navigation at its meeting in Paris had agreed to the principle that women should be eligible for the Pilot's B Certificate, but had referred to their Medical Sub-Commission the question of modifications in the medical examination requirements necessary to make them applicable to women. The National Corresponding Secretary of the Medical Women's International Association reported that the medical women of Canada, and still more recently those of Mexico, had formed associations which had joined the International Association. A new standing committee on public health was formed to watch public health developments, including posts advertised. On the evening of June 18th a conversazione was held by the London Association of the Federation in the British Medical Association House. Sir James and Lady Berry each gave a short lecture to a large and appreciative audience.

ANTHRAX FROM SHAVING-BRUSHES

ONLY one case of anthrax from shaving-brushes has occurred since the beginning of this year, happily without fatal result. The Minister of Health stated, in answer to a question in the House of Commons by Mr. J. B. Couper, that all practicable steps have been taken to trace shaving-brushes which have been imported into this country from the same source, with a view to their being destroyed or withheld from sale. Steps have also been taken to deal with any future consignments of shaving-brushes from this source, and the matter has been referred to the Government of the country of origin in order that appropriate action may be taken.

cocci which would ordinarily be expected to produce cortical lesions may fail to do so and may pass through the kidney to produce lesions in the pelvis stroking the parenchyma of the kidney only very lightly, if affecting it at all

The Lesion.

Now, briefly, I want to discuss the lesion This undoubtedly involves the kidney, but in a transient way. Specimens are seldom available because even the acute forms of the infection are very rarely fatal and the only specimens are those from patients who die from other causes Microscopic sections of such kidneys show very few lesions of the parenchyma; there is only what the pathologist would describe as cloudy swelling The chief lesion is of the mucous membrane of the renal pelvis and the ureter and the bladder may be involved. The common result is great thickening and infiltration of the submucous connective tissue. This is a lesion which not rarely lasts for a quarter of a century, and produces stiffening of the renal pelvis Where the lesion is present over a long period, a high grade of destruction of the kidney may result, but the extraordinary thing is how long this disease can go on yet leave the patient with a functionally fair kidney

INCIDENCE AND ÆTIOLOGY

It is extraordinary to what an extent this disease in childhood, affects the female more than the male It is probably true that there are at least nine or ten cases in the female to one in the male It is a very uncommon lesion in the male child and an exceedingly common lesion in the female child In the adult, there is again a great disproportion between the male and the female, largely due to the tendency of the disease to occur during pregnancy If this group of cases were ignored the remainder would probably show very little difference in adult life But as regards sex on the whole allowing for the number of children and the number of women in whom the disease occurs during pregnancy, the disproportion between the male and female is about one to three.

As to the source of infection I am perfectly aware that I am on highly controversial ground and what I say must be taken as an opinion rather than a fact It has been said to be urogenous in origin, by which is meant the same thing as an ascending infection. It has been assumed that the disease begins with an infection of the bladder and ascends to the renal pelvis How does bladder infection arise? The advocates of the theory of ascending infection have alleged that the anatomical peculiarities of the female urethra are its source They would have us believe that bacteria proceed backwards along the urethra and infect the bladder. That view is not supported by the evidence You can introduce bacteria into the bladder you can even go further and produce trauma of the bladder, but infection will not occur And yet we were asked to believe that the infection is produced by the mere passage backward of these organisms to the bladder

There was a tendency some years ago to fall back upon the lymphatics as a source of transference of infection from the bladder to the kidney, overlooking the fact that there are no lymphatics which proceed directly from bladder to kidney. It seems to me that the advocates of the ascending theory ask us to grant them too much. They ask us to grant premises which are not certainly true and they do not put forward any method of explaining the gaps in the evidence

The only other theory which is supportable by evidence is that this infection reaches the kidney through the blood stream Now we know that the other type of infection the cortical type caused by the pus-producing cocci is always hæmatogenous in character. Why should we assume that one type of infection is produced via the blood stream and the other type in an entirely different fashion?

In the days when the hospitals used to be full of typhoid fever we commonly found the bacillus in the urine, and it was frequently possible to make the diagnosis in this way The typhoid bacillus and the colon bacillus are much alike, and it is not too much to assume that both these organisms reach the kidney through the circulation The source is the intestinal tract In ulcerative colitis one commonly sees the pyelitic type of infection of the kidneys and it is quite certain that the organisms enter the blood from the intestine under conditions below the level of what we can describe as a clinical entity and that they commonly circulate in the blood without producing symptoms recognisable by the patient.

INFECTIVE FOCI.

With us in America an attempt has been made to relate this type of infection of the kidney to distant foci As many of you realise this is the day of foci, and teeth and tonsils fall by the wayside in our attempt to eradicate them It is true that this type of infection of the kidney is relatively common in children in association with infection of the upper respiratory tract, but the organisms infecting the upper respiratory tract are never the organisms which infect the kidney It seems to me that while it is an attractive doctrine that foci in one part of the body should produce lesions in another, and while Rosenow has been successful in producing lesions in the kidney by the introduction into animals of organisms obtained from tooth-root foci, these are not the organisms with which we are here concerned They are cocci streptococci, and do not produce the type of lesion we are talking about unless we are prepared to take the view that the colon bacillus does not produce a pyelitis, and that pyelitis is produced by streptococci which are later dispossessed by colon bacilli. I find this a difficult theory to swallow, because the lesion produced by the streptococcus is an absolutely different lesion, and the assumption that the streptococcus produces the lesion and then goes off to other fields and gives over his charge to the colon bacillus seems rather fanciful.

I think we must come to the view that colon bacilli enter the circulation from lesions of the intestine which do not rise to the dignity of a clinical entity It may be that such an invasion of the blood by the colon bacillus is much more common than we have been in the habit of believing. I suspect that these organisms circulate in the blood very frequently and a bit of evidence which leads me to that suspicion is that in a series of little more than a hundred cases of early pregnancy we found the colon bacillus in the urine in over half the cases That suggests that at a time when pyelitis is notoriously common the organisms which would be capable of producing it are also not rarely found It seems reasonable to suppose that in many cases the organisms which enter the blood either die miserably or reach the kidney and are excreted without producing any lesions. Some very capable observers believe that no organisms are excreted by a normal kidney, but it is certain that organisms are found in the urine from kidneys in which we can demonstrate no lesion and it is arguable that there is no such thing as a perfectly normal kidney. If these organisms reach the kidney relatively frequently and pass through it without doing damage, why do they ever infect the kidney? This brings up the doctrine of lowered resistance, and I wish to put forward the proposition that the type of lowered resistance which leads to pyelitis is not different from the type of lowered resistance which leads quite certainly to infection of the lower urinary tract

The typical colon-bacillus cystitis may be produced with regularity in man and animals by obstruction of the bladder followed by sudden emptying Thus occurs a prepared soil: there is lowered resistance and a condition of the bladder wall peculiarly suited to infection by this particular organism. There is an immense amount of experimental work on that subject all tending to confirm this view. It does not seem to me unreasonable to assume that a process which will produce infection in the lower urinary and varied practice The lesion I classify as subacute is, perhaps, the one more commonly classified as acute and is the most commonly seen It will occur, not rarely, in the course of a peripheral infection by staphylococcus, with symptoms of pain and tenderness, referred—generally accurately—to the region of the kidney, and with fever, sometimes maintained or sometimes intermittent. The outstanding clinical findings are an enlargement of the kidney, generally perfectly evident and therefore probably considerable, which is also tender The sign which should lead to a correct diagnosis is that, with every evidence of infection of the kidney, the urine is still normal so far as its appearance is concerned, and rarely shows any abnormality except very small quantities of albumin, an occasional red blood cell, and in the early stage, many staphylococci. These are best obtained by centrifuge and smear rather than by culture though both methods should be employed, because I suspect that many organisms which one can demonstrate in smear have been so damaged that they do not grow satisfactorily

The remaining group of cases is one to which I want especially to call attention because we all seem to have been overlooking them Since we began to recognise them a few years ago, the number of instances I have seen has increased rapidly. Many of these patients have acute infections of the upper respiratory tract, sometimes we see them after ear complications, but most frequently after nasopharyngeal and tonsillar lesions The patient, in a week or ten days, perhaps when becoming convalescent, will complain of a little pain in the back, and may complain that the window was open too much last night, attributing the pain to that

On bimanual palpation of the flank definite tenderness is found, almost always confined to one side, and this will generally increase for three or four days There will be moderate fever and the urine will contain cocci, but (in our experience of 30 cases) nothing else, not even traces of albumin At the end of four or six days it is clear that the tenderness is diminishing, and at the end of ten days it has disappeared In such cases I think there is sufficient evidence to make a diagnosis of this mild type of infection of the kidney, particularly when it is possible to find organisms in the urine The greatest interest attaches to the cases in which the temperature, having come down to normal or nearly so, begins to rise again It is at this point that we may detect early perinephritic abscess, and I am satisfied that, with the kind of observation we are now capable of giving, we should be able to reach the perinephritic abscess considerably earlier than has been done in the past

TREATMENT

The group of cases which will give most trouble, not in diagnosis, but in your view as to treatment, is the group variously classified as acute or subacute The onset is sudden, there is considerable enlargement of the kidney, there is a notable amount of fever, sometimes maintained, and sometimes otherwise, and the other kidney appears to be sound Not many years ago we were confidently advised and most of us believed, that at the point at which the diagnosis could be made of enlargement of the kidney it was our duty to cut down upon the kidney and abolish it —not a difficult operation at that stage My confidence in the procedure was considerably shaken when I noted that after abolishing the kidney on evidence—satisfactory to me—that the other kidney was sound, I later had to contribute the fellow kidney to the collection of my colleague the pathologist I suspect that these lesions are more frequently bilateral than we have been believing, that in the earlier stage the removal of the kidney which is obviously diseased throws an extra strain on the kidney which is not obviously diseased but is still the site of cortical abscess of which we have, and can have, no evidence A considerable amount of cortical abscess may exist in the kidney, and we can get no evidence of it if it is below the level of enlargement and tenderness To say, therefore, that a kidney shows no evidence of a lesion is not to say that it is sound I think that if treatment is delayed until it is clear that, unless something is done, the resistance of the patient will be insufficient to result in survival, it is more likely that the other kidney will have had an opportunity to deal with its relatively mild infection, and this delay, I think, gives better results

You may ask At what point do you decide to go ahead? This comes into the realm of what is known as surgical judgment The patient does not seem to be losing much ground, his general condition is watched to see whether there is increasing anæmia, and so on There comes a point when the patient's resistance is beginning to suffer, when the operation, though it is not a great one, must be done at once if it is to be done at all. Generally this point is reached later than most of us think, and I have been surprised how well these patients carry on, with all their symptoms for a month or six weeks At the end of that time, I think, we stand a better chance of success than if we go ahead at earlier stages

---

PART II

PYELONEPHRITIS

The type of kidney infection which I shall discuss to-day is the so-called pyelitic type, the condition commonly called pyelitis

It is probably true that, from the point of view of the pathologist, pure pyelitis is an unknown disease—that pyelitis is almost always pyelonephritis The infection of the kidney probably occurs at the early stages, and largely disappears, it is not a very important lesion and the chief force of the infection is expended on the renal pelvis In this type the infecting organism, in three out of four cases, is of the colon-typhoid group We see less of typhoid fever than formerly, so that the pyelitis of typhoid fever is becoming rather a curiosity, but the other organisms of the group behave in relation to the kidney in very similar fashion These organisms comprise a very large number of varieties Many of us have believed—I have believed—that typical pyelitis, so-called was habitually produced by bacilli of these groups It is now clear that this is not true, and that other organisms may cause pyelitis My opinion was much influenced by going over, last December some three hundred cases in which very careful bacteriological studies of the urine had been made Organisms of the colon bacillus group were responsible for the condition in 76 per cent of the cases, in the remainder various cocci were found, including *Staphylococcus aureus* The staphylococcus commonly causes a suppurative cortical lesion, but there are conditions of varied virulence in which it will behave as do the non-pus-producing organisms of the colon-typhoid group There are also various streptococci, indistinguishable by us from the streptococci causing suppurative cortical lesions, which will produce typical pyelitis

Perhaps the reason why the *Staphylococcus aureus* and its allies commonly produce suppurative cortical lesions is that they have been producing lesions elsewhere, at more or less the same time, of a suppurative type Let us imagine a streptococcus which has been producing not a suppurative lesion but a catarrhal lesion short of actual pus-production When it gets into the circulation I think it will behave as do the other organisms which commonly produce chronic catarrhs notably those of the colon bacillus group It is somewhat a question of virulence and possibly—I throw this out as a suggestion—a question of the company the coccus has been keeping, where it has been living, and what soil it has been cultivating in the recent past It is clear, I think, that organisms are modified by the tissues on which they are growing, and perhaps by the combinations of other organisms with which they are associated It is clear, also, that organisms which normally produce an acute abscess may not do so under unusual conditions That seems a reasonable explanation of the undoubted fact that (*b*) loss of tone (2) The time relations of the two halves of the diaphragm during the induction of paralysis (3) The response to stronger respiratory impulses and the influence of costal or thoracic movements—i e, of respiratory muscles other than the diaphragm (4) The course of events during recovery from compression

1 (*a*) *The amount of pressure necessary to block conduction of respiratory impulses in the phrenic nerve* This was found to vary with the duration of the pressure For example, a weight of 400 g applied to 4 mm of nerve paralysed the muscle supplied by it in 10 minutes; a weight of 80 g applied to the same length, in 1½ hours

An air pressure of 1100 mm Hg applied to 6 mm of nerve paralysed the muscle in 13 minutes, an air pressure of 100 mm Hg applied for 50 minutes produced a partial paralysis, the excursion of the muscle being reduced by 12 per cent

The results in general show that the pressure necessary to cause paralysis varies inversely with the duration of application The amount of pressure exerted by pathological conditions on the phrenic nerve during life is not known Since, however, the smaller pressures used in these experiments are comparable with the diastolic pressure in an artery, and were found effectual, though only acting during the short time allowed by experiment, we can assume that growths, glands, or fibrous tissue, acting over much longer periods, can easily exert sufficient force to block the passage of nerve impulses

Systematic measurements of the size of the nerves compressed were not made, but practical difficulties in obtaining complete conduction block in the nerves of large-size animals demonstrate that a relationship exists between bulk and compressibility. This was also found to hold good in some supplementary experiments with gastrocnemius-sciatic preparations from the frog and toad This relationship between bulk and compressibility has a clinical bearing in that it may explain why small nerves, the phrenic and recurrent laryngeal, show the effects of compression by glands, nodules, &c, more frequently than do the larger trunks of the brachial plexus

(*b*) *Loss of tone in the diaphragm following compression of the phrenic nerve* Sherrington[5] has suggested that the diaphragm is in a state of "postural contraction" or "reflex tonus" at the end of expiration, and it is in this sense that the term "tone" is used Tone, then, being the residual degree of contraction persisting in the muscle at the end of expiration, a diminution is indicated by a greater degree of elevation of the domes in the thorax, and a unilateral defect can only be estimated by comparing the expiratory level of the experimental side with that of the control side

When one phrenic is rapidly compressed in the neck the corresponding muscle loses tone and rises higher in the chest This is indicated on the kymograph by the raising of the level of the lever above the previous expiratory level, and can be confirmed by inspecting the abdominal surfaces of the domes Ken Kuré,[6] who took X ray photographs to demonstrate the position of the diaphragm, has stated that the diaphragm does not lose tone when one phrenic is cut, but with this I am unable to agree

When the nerve is blocked quickly—e g, in a few seconds—the loss of tone, as shown by the rapid elevation of the lever, is very striking, if the blocking process is spread over a period of three hours or more the loss of tone is not so readily demonstrable, but can still be shown by a comparison of the expiratory levels of the two levers, before and after compression Following quick compression the total amount of elevation is distinctly greater than after slow compression This suggests that a compensatory mechanism of some sort may come into play if paralysis is not produced too rapidly In the early stages of compression a diminution in contraction can be noted before any loss of tone

Certain physiological considerations introduce complications in clinical work It is recognised that the level or postural tone of the diaphragm varies under normal conditions, and that differences can occur between the two sides Further, the level is subject to extrinsic influences, such as gaseous distension of the stomach Temporary elevation can be differentiated by the fact that the movements of the two sides are synchronous Hence there is no hard-and-fast normal expiratory position, and an X-ray picture would show very little difference in the levels of the two sides in a case of unilateral paralysis if taken at a time when a low degree of tone obtained on the sound side

2 *The time relations of the two sides* When compression is carried out slowly, the contraction of the muscle on the experimental side is cut down smoothly and gradually, until a very small movement of the lever remains Before compression the movements of the two levers are synchronous, but as nerve conduction fails a progressive delay in the downstroke of the lever is seen, indicating delay in the commencement of inspiratory contraction The onset of delay varies in different animals, and may not be apparent until the contraction has been reduced by 50 per cent. This delay becomes more and more marked until, when paralysis is complete, the levers move inversely —i e, "paradoxical contraction" The extent of this latter movement appears to depend on the degree to which the costal part of the inspiratory apparatus is brought into play In old animals with small thoracic expansion the movement of the level on the experimental side may become so small that the time relations cannot be defined The paralysed muscle is practically immobile

If dyspnœa causes a large thoracic action the passive movement on the paralysed side may be as large as the active movement on the healthy side, though in an opposite direction Inspection of the abdominal surfaces of the diaphragm in such a condition shows a remarkable lop-sided action, the paralysed side ascending during inspiration as sharply as the healthy side descends

The levers attached to the muscle appear to move inversely before they actually do so, a fast tracing revealing only a very marked delay. In several experiments it was thought that complete block had been attained, because the movement on the experimental side was small and apparently inverse, and there was also appreciable loss of tone On section of the nerve, however, the movement became completely inverse to the sound side, and a further loss of tone occurred If, on the other hand, compression was maintained until the block was complete, section of the phrenic made no difference either to the time relations or to the elevation

Under the more difficult conditions of X ray examination the same thing may happen, and delayed action may suggest reversed movement, leading to a diagnosis of complete paralysis before the block is absolute.

3 *The response to stronger respiratory impulses and the influence of costal or thoracic movements* Under X ray examination, in certain cases of unilateral paralysis, if the patient be requested to take a deep breath an increased movement is observed on the paralysed side, the timing of which is difficult This could be explained as due to a contraction of the affected muscle in response to stronger respiratory impulses which had succeeded in forcing their way past the nerve-block On the other hand, it might be due to an exaggeration of the passive movement imparted to the diaphragm by the lungs and chest. since the main effect of a deep voluntary inspiration is an increased costal movement It has long been accepted that quiet, normal respiration is carried out mainly by the diaphragm, while "all difficult, sudden, and extraordinary breathing is costal" (J Hutchison[7])

The first possibility was tested by producing temporary hyperpnœa in the animal by means of CO_2 inhalation or faradic stimulation of an afferent nerve It was found that the resultant stronger impulses were no more effective in producing an active tract will also produce infection in the upper urinary tract. At least in some people who most commonly have this infection, some degree of obstruction of the upper urinary tract is common It should be remembered that in this disease the urine is a very satisfactory medium for bacterial growth, and it is only necessary to assume that there is in some portion of the upper urinary tract a place where stagnation of urine occurs Stagnation is much more likely to occur in the female than in the male Stagnation does occur during pregnancy, and there is accumulating evidence to show that there is abnormality of the right ureter during pregnancy in a considerable number of women. When work along that line can be carried out on a large scale, it may be shown that there is constantly some obstruction in one or both ureters during pregnancy

Here, then, is a possible method of explaining this type of infection It is notoriously true that dilatation of the renal pelvis is relatively common in the female It is further true that in the male the disease is more likely to occur in individuals of the long-bodied type, with the flat renal fossa—people in whom there is liability to visceroptosis

Clinical Types

Of the clinical types one may properly distinguish the acute, the subacute and the chronic pyelonephritis I use the word pyelonephritis, though recognising that the word pyelitis is in common use and has the dignity of long usage Amongst children and adults these acute cases are seen with fever, occasionally chills, malaise, and the loss of appetite and other symptoms which go with fever of any sort There is discomfort referred to the region of the kidney, rarely pain, moderate tenderness of the kidney, and pus in the urine This is one of the important points of distinction between this type of infection and the cortical type In the cortical type the lesion has no immediate relation with the excretory passages of the kidney, and consequently pus does not appear in the urine In the pyelitic type pus appears in the early stage and with it the characteristic organisms of the colon group, readily to be found in the fresh specimen, or in the stained specimen, where they will be seen to be large bacilli They cannot be classified by staining, but it is possible to be almost certain that the organisms belong to the group

In some of the acute cases the fever is very high and the patients look very ill Those with a blood-thirsty type of mind have difficulty in restraining their inclination to resort to surgery The kidney is often moderately tender and the patient is very ill, and it seems as if something ought to be done to rescue that kidney from destruction by infection As a matter of fact the disease is so rarely fatal that the possibility may be forgotten except during pregnancy The patients recover, but the disease can continue as a chronic pyelitis over a long period of years The more acute the attack, the more certain it is that complete recovery will occur It is in the milder cases—those in which there is no concern about the life of the patient—that there is more likelihood of the condition becoming chronic

Particularly in children, but not rarely in adults, the onset may be so mild that nobody knows when it started It is probably true that the majority of children who are brought to a physician with pyelitis can give no account, and their parents can give no account, of the onset of the disease It has been noticed that the child is a little less bright and active than usual, but nothing has been thought of it, and the disease is discovered only through an examination of the urine In fact, pyelitis was considered rare in children before routine examination of the urine became a common practice These cases may be described as chronic from the start, and the probability of their continuing is much greater than when the onset is acute It is this group of cases, particularly in children which gives the greatest concern, because they will go on in spite of most forms of treatment, and, so far as I know to-day, there is no form of treatment which will certainly influence the course of the disease It would be interesting to inquire whether the disease occurs in adult life, as pyelitis of pregnancy, more commonly in women who have had pyelitis in childhood than in other women As far as I know, no group of cases has been studied with sufficient accuracy to settle the point

In the cases in children which are chronic from the start, or which take on a chronic character, there is an increasing opinion that there is abnormality of the kidney This indicates very directly the need for investigating these kidneys, as it has not been possible to investigate them in the past I think we are required to-day to examine the kidneys of children with chronic pyelitis with the same care that we examine the kidneys of adults and to-day this is possible with the smaller instruments which are available In many cases definite abnormalities will be found, and at least in some of them, methods of treatment short of operation can be employed The point I want particularly to impress on you is that we should not be satisfied, when the diagnosis of chronic pyelitis in children has been made, with treatment by medicinal agents, hoping that there will be recovery either as a result of the medicine or by the mere lapse of time So many of these cases have already been shown to have definite abnormalities that we ought not to rely on the methods of a different day.

UNILATERAL PHRENIC PARALYSIS

CLINICAL APPLICATIONS OF AN EXPERIMENTAL STUDY

By GRACE BRISCOE, M B , B S Lond.

The clinical justification for this experimental study will be found in a paper by Charlton Briscoe[1] on the syndrome of signs and symptoms arising from unilateral phrenic paralysis In this he shows that the condition is really far from uncommon and indicates that in many cases whether primarily due to malignant growth enlarged glands, or inflammatory fibrous tissue, the essential cause of the paralysis is simple mechanical pressure on the nerve What one would expect to provide the most certain means of clinical diagnosis—namely, the behaviour of the diaphragm as observed with X rays—was found, however, to give such indecisive results in some cases that confusion exists in this respect Radiologists are far from being of one mind as to the typical screen picture produced by paralysis of one half of the diaphragm[2] [3]

It seemed desirable, therefore, to carry out an experimental investigation into the behaviour of the diaphragm following simple mechanical pressure applied to the phrenic nerve on one side

Experimental Methods

Only a brief outline of the experiments is given here Details are recorded in the *Journal of Physiology*[4]

The movements of the two halves of the diaphragm of the cat were recorded on a moving, smoked paper by means of levers connected by threads and small hooks to the abdominal surfaces of the domes (cupolæ) Inspiration caused a downward movement The movement of the intact thorax was simultaneously inscribed This method of recording the action of the diaphragm was chosen because the outline of the domes is the part observed *in X ray examination* While the movements of the diaphragm and chest, in response to natural respiratory impulses, were being inscribed on the kymograph, pressure was applied to one phrenic, after dissection in the neck, and the result of blocking conduction in the nerve was seen in the altered movements and level of the dome on the corresponding side

Particular attention was paid to the following points as they have some bearing on the clinical aspects of unilateral paralysis (1) The amount of pressure required to cause (*a*) loss of contraction,

ON SOME EFFECTS OF PRIMARY AND SECONDARY X RAYS UPON THE SKIN OF THE FROG TADPOLE *

BY HECTOR COLWELL, M B LOND , D P.H OXF ,
DIRECTOR OF THE RADIOLOGICAL DEPARTMENT, KING'S COLLEGE HOSPITAL ,

AND

M SYDNEY THOMSON, M D , M R C P LOND ,
PHYSICIAN TO THE SKIN DEPARTMENT, BELGRAVE HOSPITAL FOR CHILDREN

IN October, 1923, the present authors, in collaboration with Mr C P G Wakeley, F R C S , published a note on the effects of the prolonged action of X rays upon the skin of the frog tadpole [1] Consisting as it does of but two clearly differentiated layers of cells the epidermis affords an admirable medium for the observation of changes occurring as the sequel to irradiation, more especially when these are hypertrophic in character It is, moreover, a young and actively growing tissue, and therefore responds well to the action of the rays.

Under normal conditions the two epithelial layers are clearly differentiated from each other and from the subjacent corium The superficial layer of cells is somewhat flattened, the outlines of the cells of the deeper stratum are more or less polygonal, while the nuclei roughly correspond in shape to the outlines of the cells The cell outlines are remarkably well defined and, indeed, present many of the appearances of typical cell walls, even to distinct thickenings in the angles between contiguous cells (Fig 1)

The corium varies greatly in depth, but it is never so wide as to exceed the width of the epidermis Its structure is nowhere very obvious, since it stains as a more or less homogeneous pink mass, although a meshwork of white fibrous tissue and a network of elastic fibres can be more or less indistinctly seen A few oval or polygonal cells are also seen , these give off numerous finely branching processes and have large nuclei with well-defined nucleoli It is, however, the large pigment cells which constitute the most obvious feature of the corium Generally speaking, these are deep in position and lie close to the muscle bundles They vary considerably both in size and shape and usually have very distinct arborescent processes

Throughout our experiments we made use of an ordinary Coolidge tube and the induction coil employed in the routine therapeutic work of the hospital Variations in the conditions of working were made in different series of observations and will be duly noted as occasion requires The tadpoles were exposed to the rays in circular flat-bottomed dishes containing water or dilute mixtures of colloidal element and water

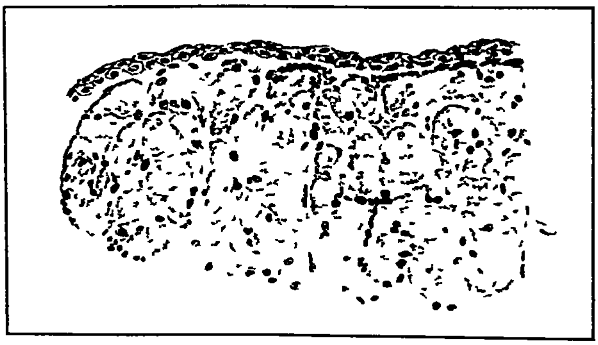
Group I.

Tadpoles irradiated in ordinary tap water Coolidge tube working at 2 milliamperes with a 7-in spark-gap Distance of anticathode from surface of water 6½ in Depth of liquid in glass dishes, 1½ in The tadpoles were divided into three batches and irradiated for 1½, 2, and 5 hours respectively Individuals were killed at different periods after exposure, fixed in 50 per cent alcohol, and after the usual preliminary processes, cut in paraffin in the ordinary way The stain employed was hæmatoxylin and eosin

Here the most obvious sequel to exposure was a hypertrophic change which, in specimens removed immediately after exposure, was only suggested by increased nuclear activity in the "1½-hour" specimens, but was clearly demonstrable in the "2-hour" specimens, while in the "5-hour" specimens, although hyperplastic areas could be differentiated, the main picture was one of degeneration

Specimens Killed 24 hours after Exposure —Here the "1½- and 2-hour" specimens showed progress in the hyperplastic process as shown by increased nuclear activity and cell proliferation, which caused a loss of demarcation between the superficial and deep epidermal layers The hyperplastic process was accompanied by a loss of cell outline, so that the appearance was that of a syncytium, which was associated with a quite definite invasion of the corium The "5-hour" specimens, although showing traces, or rather remains, of hypertrophic processes, presented generally the appearances of degeneration The syncytium formation, to which reference has just been made, is a characteristic feature of the hyperplasia occurring in tadpole epidermis as a sequel to irradiation, cell outlines being completely lost and a multinucleated mass of protoplasm resulting

FIG 1



Section across integument and underlying muscle of normal tadpole Note the epithelium consisting of two clearly differentiated layers of cells

Specimens Killed at Later Periods after Exposure—The hyperplastic changes in the "1½-hour" specimens would appear to reach their maximum in about 84 hours after exposure , after that the changes are retrogressive in character, so that specimens examined seven days after irradiation show complete epidermal atrophy In the "5-hour" specimens this atrophic condition was found 96 hours after exposure Thus the description of the '1½-hour" specimen examined seven days after irradiation is as follows ' There is complete atrophy of the epidermis, which is represented merely by a wavy line with a few small local thickenings The line consists of an evenly stained strip which has taken up the eosin and hæmatoxylin approximately equally and so presents the appearance of a narrow, evenly stained lilac ribbon "

Group II

Conditions as before, but a small quantity of *protargol solution* added to the water in which the tadpoles were exposed, so that the total concentration of protargol was about 0 04 per cent Distance of anticathode from surface of liquid, 6½ in Depth of liquid, 1½ in In this case the tadpoles were exposed not only to the primary beam of X rays directed upon them from the Coolidge tube, but also to the secondary radiations from the finely divided silver dispersed throughout the medium in which they were exposed. All were exposed for two hours

Specimens Examined Immediately after Exposure —All the cells were somewhat small and appeared a little shrunken. Signs of hyperplasia were, however, present both in the epithelium and in the connective tissue elements of the corium.

Specimens examined 48 hours after Exposure —These specimens exhibited hyperplasia of the epithelial cells to a much greater extent than had been seen in any examples

---

* The expenses of this research were defrayed by a grant from the Medical Research Council

contraction on the affected side than were the weaker impulses of quiet respiration

The second possibility was confirmed by experiments in which the animals spontaneously took deep inspirations Before pressure these deep inspirations showed as slightly increased downward movements on both sides of the diaphragm, while the thoracic expansion was markedly increased During complete paralysis there was inverse movement of the two halves in quiet breathing On deep inspiration a greatly increased upward (therefore passive) movement occurred on the affected side, and a slightly increased downward movement on the sound side In the intermediate stage of partial paralysis the contractile power of the muscle was diminished, but not destroyed The experimental side still descended in quiet, normal inspiration, though its action was much delayed When hyperpnœa or a single deep inspiration occurred the paretic muscle was unable to resist the increased intrathoracic pull and was moved passively upwards

The experimental evidence, then, shows that any increased movement appearing on the paralysed side when a deeper breath is taken is not due to a nerve impulse which has forced its way past the pressure block, but is produced by mechanical factors

The possible expansion of the human thorax in its lower part is relatively less than that of the cat, and the changes seen under X ray examination are not likely to be so marked as these animal experiments suggest In these, as in patients, it was found that the older the subject the less was the costal movement, because of the greater rigidity of the thorax A mobile thorax clearly can produce greater and more sudden changes of intrathoracic pressure than one which is relatively fixed In addition the effect of the anæsthetic has to be considered as accentuating the depth of respiration in general

4 *Recovery* The recovery of contractile power occurs as smoothly and gradually as the diminution in movement is produced Recovery of contraction always precedes recovery of tone Although, on various occasions, the experimental side has been seen to move as well after compression as before, it has not been possible to prolong an observation for sufficient time to see if complete recovery of tone takes place

The recovery from birth palsy is interesting from this point of view Injury to a phrenic nerve at birth, causing unilateral paralysis, is occasionally seen as a result of pressure by forceps Reports of such cases giving fluoroscopic findings are rare Kofferath[8] has reported a case which showed the typical X ray picture of paradoxical movement and marked elevation on the right side At the age of 4 months the respiration had become completely normal, the diaphragm moved equally and synchronously on the two sides, but the right side was still somewhat above its normal level Friedman and Chamberlain[9] have also reported a case of right-sided palsy In their case respiratory disturbances were more marked and prolonged The paradoxical movements on the injured side were only slightly less than those on the healthy side At 3 months of age the respiration had become normal At 8½ months the fluoroscope showed that the two sides were moving synchronously, and with the same range of motion, but that the right side was still a trifle, about half an interspace, above the normal level

If compression is stopped directly the signs of paralysis have appeared, recovery of movement occurs very rapidly—i e , an improvement in contraction may be noted within a few seconds This confirms the notion that the mechanical compression is the essential cause of the paralysis If pressure is excessive, or maintained after paralysis is complete, recovery is delayed.

Summary of Experimental Conclusions

1 The functions of tone and contraction are separate factors, and are affected in different degrees by pressure on the phrenic nerve

2 Experimental pressures comparable to those occurring in the body can obstruct the respiratory impulses in the phrenic nerve

3 The amount of pressure required to produce paralysis varies inversely with duration of application

4 The longer the time taken in compression of the nerve the less obvious is the loss of tone, as indicated by elevation, suggesting the development of some compensating mechanism which has not been studied

5 Complete nerve-block is shown either by reversed movement or by immobility, the latter occurring when the thoracic expansion is small Elevation is present in varying degree

6 Incomplete nerve-block is shown by diminution of inspiratory descent, and by delayed action on the affected side This unilateral lagging becomes obvious in the later stages

Clinical Applications of Experimental Results

The appearances one would expect to find in an X ray examination of a clinical case of paralysis of one-half of the diaphragm are —

(*a*) An elevated position of the affected side due to loss of the tone or postural contraction which normally prevents complete relaxation

(*b*) " Paradoxical contraction " or " reversed movement "—i e , ascent of the affected side during inspiration, while the healthy side descends, because the paralysed muscle cannot resist the aspiration of the chest, and is moved passively

This typical appearance was seen in some of Charlton Briscoe's cases, and was found by Woodburn Morison[10] to be constant in " eventratio diaphragmatica," a congenital condition in which the muscular tissue on the affected side is underdeveloped The difficulty was to explain why in many undoubted instances of acquired paralysis reports were received, such as " slight movement," " scarcely any movement," and elevation was by no means constant There are several instances in the cases of acquired paralysis described by Morison where the elevation was only slight

It is now possible to state that—

1 Pressure does not abolish contractile power suddenly, but reduces it gradually Hence, if paralysis be partial, contraction will only be reduced in proportion, and every grade between slight diminution and complete inverse movement can occur

2 Reduction in extent of contraction is accompanied in the later stages by delay in action Hence, the time relationships between the two sides are altered, and in the absence of other pathological conditions unilateral lagging should suggest the possibility of pressure on the phrenic nerve

3 Diminution in " tone " does not run a parallel course with diminution in contractile power Hence, elevation in the thorax need not be proportional to loss of contractile movement

4 In cases of gradual onset the effects of loss of tone (elevation) may be modified by some compensatory mechanism This tends further to increase the disproportion between elevation and diminution of contractile movement

Considering all these points together, it seems clear that cases of complete unilateral paralysis occurring in young patients with free thoracic movement will provide a typical appearance of inverse movement and elevation In older patients, in whom the thorax is more fixed and the lungs less elastic, these appearances will be less marked Cases of partial paralysis, on the other hand, cannot be expected to present a precise diagnostic picture, but will yield apparently indefinite results This explains the varied reports received about many of Charlton Briscoe's patients, and leads to the final conclusion *that a majority of the cases met with in clinical work are instances of partial—not complete—paralysis*

bodies contained within the cells, these sometimes assume a digitate appearance, or they may resemble barbed arrow-heads The former is the more characteristic, and its mode of formation may be deduced from the appearances of several cells in the section from which Fig 3 was drawn In these cells the protoplasm immediately surrounding the nucleus is seen to contain a very finely divided pigmentary deposit, while the protoplasm itself has assumed a figure somewhat reminiscent of an aurora borealis There is a "dusty" area immediately surrounding the nucleus, and from this central body radiating "fingers" emerge Between this stage and the finished brown figure many intermediate forms can be detected It would thus seem that the curious shape is due to a "scaffolding" formed by the protoplasm, and is not formed by any characteristic crystallisation of the silver. That this deposit is silver and not melanin has been demonstrated in other sections by the ordinary photographic processes of bleaching out with potassium ferricyanide and sodium thiosulphate Slight "development" was obtained with hydroquinone, and "intensification" by treatment with mercuric chloride followed by ammonia This hyperplastic change far exceeds any seen in all the specimens we have examined

Lead (16 days), *Bismuth* (16 days) Main changes degenerative in character, with traces of hyperplasia The changes generally are less marked in the "bismuth" specimens

Tadpoles irradiated as before, but strength of mixture in which they were irradiated was 5 per cent instead of 10 per cent —As previously mentioned, the 10 per cent gold mixture was for some reason or other too toxic for the specimens to remain in it for more than a few minutes Some exposures were therefore made in 5 per cent mixtures

After 48 hours Markedly hypertrophic changes were found, especially in the epithelium covering the limbs and tail After 8 days Hyperplasia was marked in the limbs and tails and all distinction between the epithelial layers lost The superficial cells exhibited signs of keratinisation, while centrally syncytium formation was evident After 20 days The outstanding features were those of degeneration, but remains of hyperplasia and syncytium formation were still evident in the basal layer

The colloidal elements used in 5 per cent mixture were copper, selenium, gold, lead, and bismuth The temporary hypertrophic changes in the gold specimens have just been noticed Irradiation for 1½ hours in the presence of 5 per cent copper mixture led to destructive and degenerative changes, with only here and there suggestions of hyperplasia With selenium the results were much the same, but small hyperplastic areas were more definite With gold, as just seen, the hyperplastic changes were well marked for a time, but succeeded by degeneration With lead and bismuth degeneration and atrophy predominated, but some hyperplasia could also be made out

Conclusions

Throughout the series of experiments we have described the tadpoles were, of course, exposed to the general beam of mixed radiations from the Coolidge tube as well as to the secondary radiations from the admixed colloidal elements It has also been shown that the effect of exposure to the primary X rays from the tube (in the absence of any added colloid) is to produce a fairly marked temporary hypertrophy followed by degeneration Yet taking these factors into account it would appear that the secondary radiations from copper are mainly destructive in character as are also those of selenium though here the destructive changes are less apparent and the evidence of temporary hyperplasia are more marked

In contrast with these changes are the effects produced by irradiation in the presence of colloidal silver, where the hypertrophic changes are predominant and exceed in amount those produced by irradiation in the presence of any other colloid used while their persistence is also equally striking Irradiation in the presence of colloidal gold (5 per cent mixture) also produced marked hypertrophic changes, more especially on the limbs and tails of the embryos Next to those caused by irradiation in the presence of silver, these were the most marked hyperplastic changes we observed In the lead and bismuth series hyperplasia was less marked and disappeared sooner than in the silver or gold series

The results suggest that the extraordinary hypertrophic changes due to irradiation in the presence of colloidal silver are due to some special action of some of its characteristic radiations; and as these changes are still very well marked in the case of gold, that probably some series of wave-lengths are specially concerned in producing this hyperplasia

SYPHILIS OF THE HEART AND AORTA *

BY FREDERICK W PRICE, M D F R S EDIN,
CONSULTING PHYSICIAN, ROYAL NORTHERN HOSPITAL, PHYSICIAN,
NATIONAL HOSPITAL FOR DISEASES OF THE HEART

THE subject of syphilis of the heart and aorta is one of great importance, and also one of great difficulty, more especially with regard to the relative frequency, and diagnosis of the condition These are intimately bound up with ætiological and pathological considerations I shall confine my remarks to the acquired form of the disease, for the reason that the congenital form lies almost entirely outside my experience

Pathology and Relative Frequency

Acquired syphilis may attack the aorta, the cardiac valves, the coronary arteries the myocardium, the auriculo-ventricular junctional tissues, and the pericardium With regard to the aorta, Prof H M Turnbull[1] found that in 288 necropsies at the London Hospital, in which lesions of acquired syphilis were present the most common syphilitic lesion was mesaortitis This affection is the result of inflammation of the vasa-vasorum and their terminations in the external and middle coats of the aorta There is perivascular infiltration of lymphocytes and plasma cells, accompanied by periarteritis and endarteritis —indeed, in the great majority of cases all the coats are involved Ultimately the lumen of the vessels may become completely closed The adventitia and, later, the media of the areas of the aorta supplied by the inflamed vasa-vasorum are secondarily affected, and the inflammation is mainly confined to these coats The inflammation in the media is followed by absorption, and it may be necrosis, of the elastic tissue and muscle-fibres, and. at a later period, by new formation of fibrous tissue This leads to local weakening of the vessel, which may give rise to aneurysms, varying from a minute to large size The intima over the areas of inflammation is usually thickened The thickening of the intima is merely secondary, and is protective or compensatory It is due to the connective tissue laminæ being increased in size and number, often an ingrowth of new vessel formation from the media, and sometimes cellular infiltration from the other coats of the aorta In the early stages there is an absence of evidence of fatty and calcareous degeneration—a fact which may be due to the ingrowth of new vessels from the media The secondary thickening of the intima has been confused with atheroma Mott, Marchand Turnbull and others have described the distinctive features of syphilitic mesaortitis and atheroma It is necessary to point out and emphasise that this distinction is even yet not nearly sufficiently appreciated and is not even admitted by some Prof Turnbull has shown that the secondary thickenhitherto examined The epithelium generally showed an increase to about four or five cells in thickness, while in places this was sometimes exceeded The hyperactivity was fairly constant over the whole of the skin and was not limited to isolated patches Obliteration of cell outlines was frequent, thus giving rise to an exaggerated picture of the syncytium formation produced by simple irradiation in water without the addition of protargol Corresponding increase in activity was also shown by the connective tissue cells of the corium, which showed a marked tendency to branching, the pigment cells were small but markedly arborescent

* Being a contribution to a discussion at a meeting of the Medical Society for the Study of Venereal Diseases on Feb 26th, 1926

[1] Turnbull, H M The Quarterly Journal of Medicine, April, 1925, viii, No 31

From this it is clear that the secondary X rays from the finely divided silver had a very definite and marked effect in accelerating and accentuating those hyperplastic changes in the epithelium, which have been shown to occur as an early result of exposing tadpoles to the action of the mixed radiations from a Coolidge tube in ordinary water

It is, of course, well known that different elements when exposed to a suitable beam of X rays give off secondary radiations which are characteristic as regards their wave-length for the particular element used Moreover, these characteristic secondary X rays have definite relations to the atomic number (or the number representing the position of the element in the periodic series) and consequently to the atomic weight of the element in question We accordingly determined to carry out a series of experiments in which different elements in colloidal form[2] were added to the water wherein the tadpoles were exposed, and thereby to ascertain if the effects of the secondary radiations from other elements resembled or differed from those of the secondary radiations from silver The stock colloids in all cases were supplied in a concentration of 1 in 2000 and 10 per cent of this stock " collosol " was added to the water in which the tadpoles were exposed The atomic numbers and atomic weights of the elements thus used were as follows —

	Atomic number	Atomic weight
Copper	29	63 5
Selenium	34	79 2
Silver	47	108 0
Gold	79	197 2
Lead	82	207 0
Bismuth	83	209 0

Group III

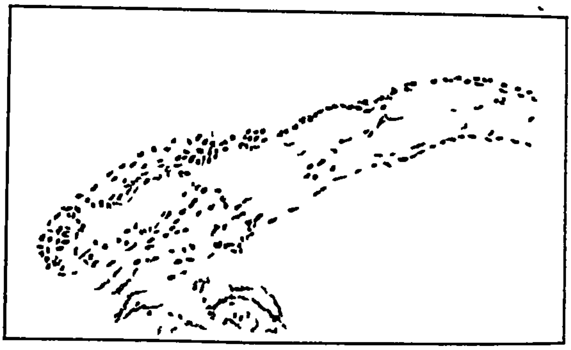
Tadpoles irradiated for 1½ hours in water to which 10 per cent of different collosols (1 in 2000) were added

In each case the anticathode of the Coolidge tube was 12 in from the surface of the liquid, while the depth of the liquid was in each case about ½ in The 10 per cent mixture of the gold collosol and water was found to be so toxic in its action that it could not be used, but a 5 per cent mixture was found to be practicable and reference to the results obtained will be made subsequently The specimens examined were as under —

Copper	Selenium	Silver	Lead	Bismuth
72 hours	72 hours	72 hours	—	—
—	96 "	—	96 hours	96 hours
17 days	17 days	17 days	16 days	16 days

Specimens Examined 72 hours after Exposure (copper, selenium, silver) —*Copper* These specimens showed only slight deviations from the normal Such changes as were found were in the direction of atrophy and there was no suggestion of hyperplasia Some vacuolation of cytoplasm and shrinkage of nuclei *Selenium* The epidermis showed degenerative changes, but not so marked as with the " copper " specimens, and in addition some few hyperplastic areas could also be detected The hyperplasia was most marked on the limbs Even in the hyperplastic areas degenerative changes had already made their appearance *Silver* The superficial epidermal layer showed no evidence of any degeneration, in the basal layer, however, were some distorted nuclear forms and vacuolated cytoplasm In some places the epithelium is increased to four or more layers in thickness The hyperplastic changes were most marked in regions where the cross section of the body was the smallest—e g, the tail or limbs—and here also the outermost layer of cells stained definitely pink and showed striation, as though some attempt at keratin formation were taking place (Fig 2)

FIG 2

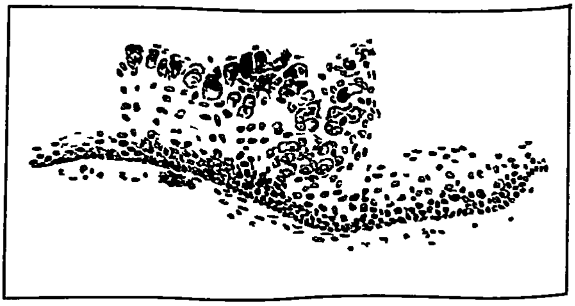


Section to show tadpole epithelium Specimen killed 72 hours after irradiation in 10 per cent mixture of " collosol " selenium. Note the hypertrophic patch to the left of the figure

Specimens Examined 96 hours after Exposure (selenium, lead, bismuth) —*Selenium* Extensive vacuolation of the epidermal cells was the predominant feature, while the small patches of hyperplasia also showed degenerative changes *Lead* The appearances in the epidermis were mainly of a degenerative character, sometimes degeneration had progressed so as to lessen the depth of the epidermis to about one-half of its normal *Bismuth* Degeneration was again the outstanding feature and no hyperplasia was seen

Specimens Examined 16 or 17 days after Exposure (copper, selenium, silver, lead, bismuth) —*Copper* (17 days) Occasional hyperplastic areas, but these are ill marked The general picture presented by the epithelium is one of degeneration, in some places this had progressed to such an extent that the cytoplasm of both epidermal layers had coalesced and stained as a homogeneous mass with occasional suggestions of degenerated nuclei *Selenium* (17 days) The general appearances much the same as in the " copper " specimens The evidence of hyperplastic change was, however rather more definite *Silver* (17 days) The most striking features are well illustrated in Fig 3 There are patches of such marked hyperplasia that they practically amount to excrescences In them all differentiation between the two epidermal layers is completely lost The cells are large, and cuboidal or oval, while the nuclei are large, stain well, and have remarkably distinct chromosomes and nucleoli

FIG 3



Section to show enormous epithelial hypertrophy Tadpole irradiated 1½ hours in 10 per cent mixture of " collosol " silver Note general epithelial hypertrophy and the definite wart like outgrowth

There are two outstanding features in the hyperplastic areas The first is the presence of elliptical cells with no obvious nucleus, and yet containing a rounded and more faintly staining body They are very suggestive of " Paget cells," and therefore of early malignancy, and thus in spite of the fact that there is no definite sign of downward growth and invasion of the corium The second feature is, however, perhaps the more striking There are many dark brown manubrium sterni and on either side of it, a systolic murmur over the aortic area; while the second sound may exhibit a musical, bell-like, or clanging quality With the X rays, the aorta may show diminished translucency and an increased diameter Alteration in the voice and tracheal tugging are occasionally to be noted

---

[2] The colloidal elements used in this research were the standard " collosols " for therapeutic use kindly supplied to us by the Crookes Laboratories, to whose chief chemist, Mr Ward, B Sc, we desire to express our best thanks

Later, the clinical picture of aortic incompetence, or of myocarditis, or saccular aneurysm may develop With regard to the first, shortness of breath on exertion is probably the most frequent symptom of all The largest group present symptoms of systemic anæmia, such as giddiness, syncope or fainting attacks, early fatigue on mental effort, sleeplessness, and headache What is often termed "cardiac asthma" is comparatively frequent Pain in the precordium is of fairly frequent occurrence. but is not so common as in aortitis Angina pectoris is relatively infrequent Indications of chronic venous congestion supervene in a comparatively small proportion of cases General œdema is only occasionally met with I would emphasise the great importance of an early and most careful search for the presence of a diastolic murmur over the base of the heart, over and on either side of the sternum, and at the apex—in fact, over the whole precordial area In the early stage the murmur is often faint, and may be audible only after emptying the chest after a deep inspiration, and may be heard on some occasions and not in others There is less tendency for the systolic blood pressure to rise, and, still more so, for physical signs of left ventricular hypertrophy to develop, than in the case of aortic incompetence due to other causes; I have observed some cases which proceeded to a fatal termination with an absence of evidence of left ventricular hypertrophy during the whole course of the illness Involvement of the myocardium may reveal itself on polygraphic and, more frequently, on electrocardiographic examination by the presence of the first or second grade of auriculo-ventricular block, and rarely by bundle-branch or intraventricular block, and, in one case of my experience, by transient attacks of auricular fibrillation If complete auriculo-ventricular block occurs, it usually does so in the later stages Subacute bacterial endocarditis may supervene Sudden death may occur, and may be due to complete and abrupt closure of the orifice, or trunk, or one of the main branches of a coronary artery, to rupture of the heart, fatal syncope, or angina pectoris

The foregoing description covers the great majority of cases It is necessary to add the following. Relative, and even complete, recovery—either the result of specific treatment or spontaneous—may occur at any period There may be exacerbations of the disease all through life Sometimes aortitis escapes notice altogether, and the clinical picture is that of aortic incompetence developing insidiously The clinical picture may be that of acute general cardiac failure, it may be proceeding to rapid dissolution Sometimes the condition is only discovered post-mortem In the early stages the Wassermann reaction is almost invariably positive, but as the disease becomes more chronic it is increasingly negative

The diagnosis is sometimes comparatively easy, but may be very difficult. In its consideration the following points, among others, require consideration The age the previous history, the history of the present illness, the subjective symptoms, the results of physical and instrumental examination, the Wassermann reaction the presence or otherwise of syphilitic stigmata, and the course of the disease With regard to the previous history, may I remind you that it is very easy to overlook a rheumatic infection in childhood There may also be a history of rheumatic and syphilitic, and even other, infection in the same patient There may be a combined lesion I would emphasise the importance of pain behind the upper part of the sternum, presenting the characteristic features described. If it has been possible to obtain a full and accurate history, it will be found that in the vast majority of cases it has been present in the early stages The pain differs from that of angina pectoris in that it is less paroxysmal, its localisation is higher, it has a far less tendency to radiate to a distance and it is more likely to come on spontaneously and not to cease completely after exertion is over The presence of a systolic murmur over the aortic area, an altered second sound in the manner described, and the result of an examination with the X rays are of considerable diagnostic importance It is necessary to exclude aortitis due to infection by pyogenic organisms of a subacute or chronic type, by the tubercle bacillus, and other organisms, aneurysm, and atheroma The last named, when limited to the aorta, however, rarely causes pain A cardiac lesion coming on in middle life, if antecedent rheumatic infection can undoubtedly be excluded, is strongly suggestive of syphilis, as also is angina pectoris occurring before the age of 40 A combination of aortic and mitral valvular disease, especially before 30 years of age, is strongly suggestive of being of rheumatic origin Atheroma much more frequently causes aortic stenosis than incompetence. A Wassermann test should be done in all doubtful heart cases, and in all cases of aortic disease—even if there is a history of acute rheumatism I need not remind you that a negative Wassermann is not so valuable as a positive reaction, that a single negative reaction does not exclude syphilis, and that in some cases it may be advisable to employ a provocative dose of salvarsan or one of the other organic arsenical preparations We should, on the other hand, be careful not to place too much reliance on the result of the Wassermann reaction; it should be considered in conjunction with other clinical data A positive Wassermann does not indicate that the malady from which the patient is suffering is necessarily syphilitic; the same applies to the coexistence of other specific stigmata There may also be a double lesion

Prognosis

This depends largely, perhaps very largely, upon early diagnosis, and the kind of treatment adopted. Taking cases as a whole. the prognosis is very unfavourable, due, no doubt, to the fact that a correct diagnosis is not often made until the later stages of the disease. I venture to hope that in future an early diagnosis will be arrived at with increasing frequency When untreated, the lesion is usually progressive. it may be rapidly so, and the mortality is high If, on the other hand, a diagnosis is made early. and treatment is prompt and adequate, especially when the patient has not received specific treatment previously there is a reasonable prospect of relative recovery, and occasionally recovery is even complete Naturally, the prognosis is much more favourable in the absence of aortic incompetence, involvement of the coronary arteries and of the myocardium, angina pectoris. and aneurysm Prompt and adequate treatment of aortitis may prevent the aortic valve, coronary arteries, and the myocardium becoming involved, and the formation of a saccular aneurysm Even in the absence of angina pectoris and aneurysm in aortic regurgitation the prognosis is usually very unfavourable, death often taking place within two or three years after the onset of subjective symptoms Two important points in all cases are the degree of cardiac failure present and its rate of advance Help is sometimes obtained from the results of polygraphic and still more frequently of electrocardiographic, examination Thus. the presence of alternation of the heart in the absence of a severe grade of tachycardia is an indication of extreme exhaustion of the heart muscle; the occurrence of partial heart-block is a sign of myocardial involvement; persistent heart-block of mild degree is also indicative of myocardial damage, bundle-branch block is usually of very unfavourable significance; and intraventricular block is usually of grave import A few cases of complete auriculo-ventricular block have been recorded in which energetic specific treatment appears to have been rewarded with ing of the intima in syphilitic mesaortitis may be distinguished from atheroma by the naked eye—by its greater latitude and prominence, its crenated outline, pearly colour, pitted surface, and rubber-like consistency The pitting and scarring are due to the replacement of the media by fibrous tissue Having pointed out these distinctive features, however, I may add that in the later stages atheroma usually occurs in the thickened intima over the areas of inflammation, this process being exactly similar to the secondary atheroma which occurs in the attack of acute endocarditis due to rheumatism , also that syphilitic mesaortitis and primary atheroma may coexist, especially in later life

The ascending part of the aorta is the most commonly affected The disease-process in the aorta may involve the aortic valve, and occasionally it extends to the base of the aortic cusp of the mitral valve The inflammation is similar to that of the aorta In the case of the aortic valve, it results in incompetence and occasionally in stenosis. Syphilitic mesaortitis may also give rise to occlusion of the orifice of one or both of the coronary arteries Syphilis may also affect the terminal branches of the coronary arteries In syphilis of the coronary arteries, the aorta is usually affected at the same time If, from any cause, the orifice, or the trunk, or one of the main branches of a coronary artery be completely and abruptly closed, sudden death, without the occurrence of structural changes, may occur , or infarction, and later, secondary fibrosis, may ensue, resulting in weakening of the cardiac wall In those cases in which, from any cause, closure of a coronary artery or one of its main branches is gradual, or is only partial, and in cases of narrowing or occlusion of the terminal branches, infarction does not take place , local anæmia results, and consequent atrophy of the muscle-cells and secondary fibrosis Gummatous deposits, with secondary fibrosis, also occur in the cardiac wall, but they are of comparatively rare occurrence It will thus be seen that in syphilis, fibrosis of the myocardium may be the result of coronary disease, or gummata Any of these lesions may involve the auriculo-ventricular junctional tissues and give rise to auriculo-ventricular heart-block Syphilis of the pericardium is of rare occurrence I myself have only seen a few doubtful cases I shall dismiss the subject in a few words The disease more commonly attacks in the form of an infiltration, with consequent formation of fibrous tissue, resulting in adhesions between the two layers of the pericardium, while in some cases there is effusion of fluid into the pericardial sac Gummata are of rare occurrence The affection is usually latent The diagnosis is sometimes possible from the discovery of the clinical features in a known syphilitic subject The prognosis depends mainly upon how early the diagnosis is made and treatment undertaken Small gummata, when treated early, respond to adequate therapeutic measures, but when fibrosis has occurred the condition is irremediable

The foregoing is a brief summary of the lesions which it is generally agreed syphilis may produce But this does not by any means exhaust this part of our subject I am well aware that we are now entering upon a field of great difficulty and even of controversy , for, among other things, the whole subject of the pathology and ætiology of arterial disease is involved But certain questions are of the greatest practical importance with regard to the relative frequency of syphilis as a cause of diseases of the heart and aorta, and differential diagnosis and treatment Thus, in addition to the fact that syphilitic aortitis may involve the aortic valve and the base of the aortic cusp of the mitral valve, is syphilis among the causes of primary chronic endocarditis of one or more of the cardiac valves ? There is no evidence that it is Again, apart from inducing secondary fibrosis in the manner described, may syphilis give rise to fibrosis of the myocardium independently—in other words, is it among the causes of primary chronic myocarditis—i e., a true inflammation ? There is no doubt that syphilis may give rise to a primary chronic inflammation elsewhere, and it would appear that congenital syphilis does so in the case of the myocardium Some authorities are of opinion that acquired syphilis may cause a patchy or a diffuse fine fibrosis independently of the coronary arteries, while others are not In any case, the histological diagnosis is very difficult even in the early stage, and is perhaps impossible in the later stage, so that it is probable that many of the cases of fibrosis of the myocardium in elderly people which are thought to be the result of syphilis are not so Or, again, and perhaps most important of all, is syphilis a cause of primary atheroma ? In my opinion it is not

Syphilis is the cause of a large proportion of all cases of aortic incompetence, and also an important ætiological factor of angina, especially under the age of 10 But I would submit that in considering the relative frequency of syphilis in affections of the heart and aorta, there is now a danger of going to the other extreme Thus, statements to the effect that syphilis is responsible for from a quarter to a third of the total number of cases of organic disease of the heart, for about three-quarters of all cases of aortic regurgitation, and almost invariably for cases of aortic incompetence in which there is an absence of a definite history of acute rheumatism should be accepted with the greatest reserve In considering the relative frequency of syphilis as a cause of diseases of the heart and aorta, we have to consider the questions of a history of syphilitic infection of a positive Wassermann reaction, and of other syphilitic stigmata during life and of the specific nature of, or the presence of the *Spironema pallidum* in, the lesions of the heart or aorta themselves, or the presence of other undoubtedly syphilitic lesions, or of a positive Wassermann, on post-mortem examination Of course, syphilis of the heart and aorta would be of very frequent occurrence if all the lesions found in the heart and aorta post mortem in those in whom there was a history of antecedent syphilitic infection or of a positive Wassermann, or even of other syphilitic stigmata, during life or even of a positive Wassermann after death, are to be regarded as syphilitic in origin It is, I hope, not necessary to point out that such lesions are not necessarily syphilitic Other evidence is required in order to be certain that a lesion is of specific origin Such are (1) the detection of the *Spironema pallidum* in the lesion itself, or (2) the specific histological character of the lesion

Symptoms and Diagnosis

In aortitis, pain is the most frequent and characteristic symptom, and it is exceedingly important to recognise it It is situated behind the upper part of the sternum, and is generally localised there, but it may radiate to the arms and neck It may vary from slight discomfort or a sensation of pressure to an intense pain It may be more or less constant or intermittent Occasionally there are paroxysms of pain, accompanied by a feeling of suffocation The pain may come on spontaneously—that is, apart from physical exertion—especially when lying down, or it may occur only on exertion , it is usually aggravated by exertion , it may not completely disappear on cessation of exertion There may be hyperæsthesia over the painful area Occasionally severe attacks of suffocation occur, and tachycardia may often be noted The pain may disappear after a few months or weeks—either spontaneously or as the result of treatment It may be followed by angina pectoris Some observers are of opinion that sometimes, during the early stage, rubbing sounds along the right border of the sternum may be noted, especially when the patient leans forward ; personally, I have never been able to detect this At a later stage there may be indications of fusiform dilatation of the aorta There may be pulsation in the neck, particularly in the suprasternal notch, and in the first and second intercostal spaces on either side of the sternum ; impairment of percussion over the by blood which had burst through from the underlying alveoli. There was no evidence of catarrh of the alveolar cells, nor was there any invasion of the alveoli with leucocytes. Sections from the left lung showed a patchy distribution of hæmorrhage in the alveoli, and in places these alveoli were partially aerated. The alveolar walls were for the most part compressed, indicating that the blood in the left lung may have been aspirated from the right lung. The left pleura was normal. Sections from the spleen showed marked congestion. The liver and kidneys were to a less degree congested.

Cultures.—Post-mortem cultures were taken from the lower lobe of the right lung and from the spleen. That from the lung grew streptococci, staphylococci, and *Bacillus coli*, while the spleen culture only grew *Staphylococcus aureus*.

In the case just described death was due to the condition of the lungs, and from the microscopical appearances the hæmorrhage must have originated from the pulmonary capillaries, but the underlying cause of the hæmorrhage is not at once obvious. Various explanations may be considered. In the first place, such a hæmorrhage might be asphyxial in origin, being produced at the time of birth. But the labour was easy, forceps were not used, nor was the nasal discharge (which presumably came from the lungs) noticed until some hours after birth. Moreover, the lungs were fully expanded, which suggests that a period of normal respiration preceded the hæmorrhage, and it is most unlikely that such a gross injury to the lung could be survived for four days and yet show no signs of inflammatory change. It would appear most probable that a slight but persistent oozing of blood occurred for three or four days, culminating in a large hæmorrhage which practically drowned the patient. No mechanical cause, such as thrombosis of the pulmonary veins or infarction of a large branch of the pulmonary artery, was discovered, although such a condition might conceivably be of lobar distribution. At autopsy the large vessels at the roots of the lungs contained no blood clot.

Browne explains his cases as the result of infection, producing a rapid turgescence of the pulmonary capillaries which the fragile fœtal vessels are unable to withstand, and which therefore rupture. In one of his cases post-mortem culture was sterile, and in the case here recorded the multiplicity of organisms cultured suggests that they may well have been post-mortem contaminations. Moreover, in this case the history of slight bleeding goes back for four days, and an inflammation of the lungs lasting for that time would be obvious on microscopical examination.

Four of the six cases to which reference has been made were premature infants, and the present case was also premature, so that it is possible that prematurity is a predisposing factor in the condition. Hess,[3] in writing of the pathology of premature infants, states that they are subject to hæmorrhage into the lung parenchyma, with consequent thickening of the alveolar septa, and terminating in an almost complete cessation of the circulation.

Finally, one must consider the condition spoken of as the hæmorrhagic diathesis of the newborn, in which spontaneous bleeding occurs usually from the gastro-intestinal tract and almost always within the first week after birth. In the literature of this subject scanty reference is made to hæmorrhage from the lungs. Von Reuss[4] and Griffith[5] both state that considerable hæmorrhages have been observed in the lungs, but whether these have been associated with hæmorrhages from other parts of the body is not quite clear. In the present case the bleeding was confined to the lungs, and would appear to be an example of a spontaneous hæmorrhage of the newborn occurring in an unusual situation.

I wish to express my thanks to Dr. Still for permitting me to report this case.

A CASE OF HEART DISEASE AND EPILEPSY,

WITH A NOTE ON THEIR ASSOCIATION.

BY R. O. MOON, M.D. OXF., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR DISEASES OF THE HEART;
CONSULTING PHYSICIAN TO THE ROYAL WATERLOO
HOSPITAL.

THE following case, which first came under my notice at the Royal Waterloo Hospital some 20 years ago, presents some features of interest.

A. L., married woman; five children; aged 35. No history of fits in the family; father had rheumatic fever.

No history of rheumatism or other serious illness. She had a fit for the first time at the age of 33. She felt quite well prior to the fit and had no more for a year; after that she had four in the succeeding year. When first seen by me at age of 35 she had a definite presystolic murmur at the apex, doubtless of old standing; the heart was well compensated and there were no cardiac symptoms.

In 1908, after being free from fits for 15 months, she had several in the sixth month of pregnancy. After this she had them more frequently, sometimes two or three in a week, but gradually they settled down to an average of about one a month. Almost invariably the fits occurred at night while she was asleep in bed, so that she did not hurt herself except for biting the tongue. There was never an aura. She continued to have fits on an average of 15 a year; sometimes several would occur in a week and then she would be free for a few months. Whenever she omitted taking bromide for any length of time the fits recommenced. For a time I tried digitalis and caffeine, strongly recommended by Lemoine in these cases, but without any particular success.

Hitherto the cardiac condition had given rise to no symptoms, but in 1918 the auricles began to fibrillate. At first there was a slight increase in the frequency of the fits, but soon afterwards they continued much the same as before. At last she began to have definite cardiac symptoms and was particularly troubled with shortness of breath. She responded well, however, to digitalis (tinct. digitalis, ♏xii., t.d.s.) while not discontinuing the bromide entirely, and after a time the fits became less frequent. Sometimes she has several in one night and will then be free for a few months. She was in the National Hospital for Diseases of the Heart in 1922, when the cardiac condition much improved, and again this year, when she was given luminal and tinct. digitalis ♏xx., o.n. In her case, however, luminal does not seem more effective than the bromides. Though the cardiac condition has decidedly lessened her physical activities, she can do a certain amount of house duties. The epileptic condition has apparently left her memory quite unaffected and her mental activity unimpaired.

Epilepsy and heart disease are two such common affections that it is not unlikely that they will sometimes be found in conjunction without there necessarily being any common cause on which they both depend.

In treatises dealing with epilepsy very little is said about any connexion with heart disease. Some writers on epilepsy, such as Binswanger,[1] have denied altogether any causal connexion between heart disease and epilepsy. Stintzing[2] comes to the same conclusion, and their view is apparently shared by other eminent neurologists. On the other hand, Gowers says: "Heart disease often precedes epilepsy and it is often the only ætiological condition to which one can relate the latter," and Mahnert speaks of *Herzepilepsie*.[3] Out of 1070 cases of epilepsy W. P. Spratling found as many as 22 per cent. with cardiac lesions, but he makes no attempt to draw any conclusion as to their relationship; while Dr. Aldren Turner, out of 980 cases of epilepsy, found not more than 1·8 per cent. with a cardiac lesion.

The only way in which epilepsy can affect the heart prejudicially is by causing a temporary cardiac dilatation, and this seems to be very exceptional. A priori it would naturally be supposed that epilepsy recovery, but as far as my experience is concerned, anti-specific treatment is of no avail at this stage

[3] Wien. Med. Woch., 1897, p. 1610.

Lastly, in all types of cases marked and surprising improvement is occasionally met with when adequate specific treatment is adopted

Treatment

The various measures which may be applicable to any form of cardiac disorder should be considered in detail Apart from these, the indication is for anti-syphilitic treatment This should be adopted in every case in which a definite diagnosis of syphilis of the heart or aorta is arrived at, even if the Wassermann reaction is negative, and in every case of disease of the heart or aorta in which there is a positive Wassermann or other manifestations of active syphilis, even in the absence of clinical evidence that the lesions of the heart and aorta are of specific origin Cardiac failure is not a contra-indication It is impossible to exaggerate the importance of the adoption of this method of treatment *promptly* It should also be *prolonged* I am a firm believer in the employment of the arsenical preparations, but only under certain conditions Their indiscriminate use is attended with danger even of grave degree, they may result in further swelling of the intima of the small vessels, and thus increase the risk of thrombosis I always recommend a preliminary course, of three weeks' duration, of mercurial inunction and of iodide of potassium by the mouth—10 gr thrice daily during the first week, increased to 15 gr. during the second week, and to 20 gr during the third This to be followed by one of the arsenical compounds administered cautiously, commencing with small doses and only gradually increasing the dosage The scheme I advise is the result of two or three conversations I have had the privilege of having with Colonel Harrison, to whom I desire gratefully to acknowledge my indebtedness This consists of a series of courses of sulfarsenol injected subcutaneously, with mercury injected intramuscularly The first course makes a cautious start with 10 cg of sulfarsenol, and the dosage is increased, in bi-weekly injections, to 24 cg, the total amount given in the first 54 days being 2 76 g in 16 injections, with 8 gr. of mercury in eight injections The reason that the dosage of sulfarsenol in the first course is cautious is that patients with syphilis of the heart or aorta seem easily to be upset at first by arsenobenzol preparations After the foregoing course of injections, potassium iodide is given for three weeks, to be followed three weeks later by a course of five injections of sulfarsenol and mercury This time it may be possible to proceed more boldly with the sulfarsenol—three injections of 48 cg and two of 60 cg Thereafter the treatment is continued with courses of 10 injections of 5 8 g sulfarsenol and 10 gr of mercury at intervals increasing from two to five months, with potassium iodide for a month at a time between the courses The treatment is continued on these lines for two years After the completion of this scheme, I suggest a three weeks' course of potassium iodide every two or three months during the rest of the patient's life This method of treatment applies also to cases of aneurysm It may be advisable to continue anti-syphilitic treatment as long as the Wassermann is positive even in the absence of other manifestions of active syphilis, for there is a risk of exacerbations all through life, and the small vessels around the principal lesions may become involved I have been surprised at the frequency with which a positive Wassermann persists even in the case of patients who, from a clinical point of view, have done well

I would urge the importance of further combined investigation by the clinician and the pathologist of this important subject

In conclusion, I wish to express my thanks to Prof H M Turnbull for his kindness in discussing with me the pathology of the subject

ACUTE HÆMORRHAGIC PNEUMONIA OF INFANTS.

By W. P H SHELDON, M D, M R C P LOND,
MEDICAL REGISTRAR, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, W C

IN an inquiry into the causes, pathology, and treatment of still-birth, Browne[1] in 1921 drew attention to six cases in which death had occurred unexpectedly in apparently healthy infants, and at post-mortem examination the cause of death was found to be hæmorrhage of variable severity into the pulmonary tissues The age at which death occurred varied from 8 hours to 5 weeks, *and in four of the* six cases death had taken place quite suddenly The only symptoms consisted of a brief blanching of the skin and epistaxis In a later description[2] of the case which lived to the age of 5 weeks, the rapidity of death is well exemplified, for the child was found dead half an hour after the nurse had changed its napkin, and at that time it had appeared quite normal In the ensuing half hour the nurse had not left the room, nor had the child uttered any sound

In some of these cases the lungs, or parts of them, were found to be solid with blood, but there was no macroscopic evidence to show that the hæmorrhage was inflammatory in origin Microscopically the bleeding was found to have taken place within the alveolar septa as well into the alveolar air spaces, and apart from some shedding of the endothelial cells, there was little which definitely pointed to inflammation In the three cases in which cultures were made. one was sterile, one grew *Bacillus coli*, and *Staphylococcus aureus* was obtained from the third The case about to be described seems to correspond sufficiently with these cases to merit the same title

A male child, the eldest of the family and preceded by no miscarriages, was born, ten days premature, to healthy parents both aged 20 years There was no obvious cause for the prematurity, the labour was easy and instruments were not required There was no evidence of syphilis in the parents, the father's Wassermann reaction was negative, and there was no family history of hæmophilia A blood-stained nasal discharge was first noticed 12 hours after birth, and persisted until admission to hospital For four days after birth the patient vomited after every feed, vomiting occurring about ten minutes after a feed had been taken The vomited material was not blood-stained

The infant was admitted to hospital when four days old under the care of Dr G F Still The patient was then collapsed, pallid, and pulseless, temperature only 96° F A blood-stained serous discharge was noted from both nostrils, and seemed to impede respiration, for the discharge was snorted from the nose on to the child's jacket Death occurred within an hour of admission

Post-mortem Examination —Premature infant, weight 3 lb 13 oz Skull, brain, and meninges normal Upper air passages contained a little blood-stained froth On removing the lungs, the upper and lower lobes of the right lung resembled pure blood clots, they were deep purple in colour, solid, of liver-like consistency, fully expanded, completely airless, and sank in water Most of the right middle lobe was normal, but there were a few small purple and solid areas in it, and two small ephysematous bullæ at its free margin The upper lobe of the left lung was normal, the lower lobe contained several solid purple patches each as large as a pea There were no thrombi in the main vessels at the roots of the lungs Both pleuræ appeared perfectly healthy and were shiny and smooth The mediastinal lymph glands were normal Heart normal Ductus arteriosus patent Spleen not enlarged, but very engorged and almost black in colour Liver appeared to be slightly congested Other viscera normal

Microscopically, sections from the right lower lobe showed the alveoli and bronchioles to be full of recent blood, the alveolar walls in a few places appeared compressed, but over most of the section they also were distended with blood, and in places there was direct continuity between the blood in the alveolar walls and that within the alveoli The hæmorrhage had obviously originated from the vessels within the alveolar walls The pleura was in places raised the markings on a measuring gauge. With such a complaint the court is at once impressed in his favour and the difficulty arises of finding an answer to the question for what kind of work is such a man fitted having due regard to his possible earning capacity. The judge requires to be satisfied on this point, he weighs the suggestions placed before him, and if he rejects them as being against the man's interests, the workman may become a pensioner for life of the insurance company concerned. It is true that the company has the power of reopening the case should it be found that the man is afterwards capable of undertaking remunerative employment. But there is little inducement for him to imperil an arrangement so greatly in his favour. Some workmen on the dole will not work if they can live without doing so. Similarly, an elderly man, with only one eye and a loss of orientation which has become permanent, is well aware that the labour market is practically closed to him.

[2] Browne, F J Ibid, 1922, i, 470

Uniocular Heterophoria.

Loss of orientation, or heterophoria in an insured workman with only one eye cannot be excluded as a factor of importance under the Workmen's Compensation Act. If permanent as a disability, revealed by the accident, it adds to the claim in the settlement for the loss of an eye, inasmuch as it reduces the working capacity and the earning capacity of the workman concerned, apart from the abolition of binocular vision.

The conditions under which it may assume a permanent form may now be considered. While binocular vision is present heterophoria in one eye commonly exists as a latent form of disturbance of muscular equilibrium such as occurs in anisometropia, where the refraction in one eye is better than that in the other. In a general sense, the better eye becomes the working eye while the more defective one functions in a state of latent heterophoria, without, however, causing any disturbance to the vision. When, on the other hand, the working eye has been removed, with abolition of binocular vision, the latent heterophoria in the remaining eye becomes manifest with the consequent loss of the power of accurate fixation, and the possible continuance of this as a permanent defect. In all cases in which a workman loses an eye in the course of his employment this contingency arises, and the only consolation to be derived from its consideration is the rarity of its occurrence.

Subjoined are the brief notes of a case in point.

A boilermaker, aged 61, in September, 1923, lost his right eye through the penetration of a piece of steel. When seen in January, 1925, four months later, the vision of the left eye was 6/24, improved to 6/12 nearly, with −0·75 cyl. and +1 sph. Orientation was still unrestored. On Nov 21st, 1925, he was seen again. About a week previously he had resumed work as a "plater's labourer." This required him to hammer in rivets. With the first use of the hammer he hit a man on the head, rendering him unconscious. He ascribed the accident to his vision becoming hazy, so that he failed to see the rivet clearly. The orientation was still defective although he admitted that a 2° prism base outwards enabled him to see more clearly. After this he ceased to do any work. He was seen for the third time on Oct. 5th, 1925. There was no change in the condition, and on Jan. 22nd, 1926, the case was taken into the county court with the result that the man became a pensioner for life of the insurance company concerned.

WORKHOUSE STATISTICS.—Information recently elicited from the Minister of Health in the House of Commons shows that the average number of persons maintained in workhouses in England and Wales was slightly smaller in the year 1924–25 than in the previous year. The figure for 1923–24 was 207,346, and that for 1925 201,895. On Jan 1st last 134,500 adults and 52,000 children under 16 years of age were being maintained in the various classes of Poor-law institutions in England and Wales. The average weekly cost per person maintained was 25s. 5d. in the year 1923–24 and 27s. 1½d. in the year 1924–25. The total expenditure in connexion with the institutions was £13,735,923 during the year 1923–24 and £14,194,151 during the year 1924–25.

Medical Societies.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION

The Health of the Professional Woman

A MEETING of this Association was held on June 8th at the house of the British Medical Association, Dr. **CHRISTINE MURRELL**, the President, being in the chair.

Dr **LETITIA FAIRFIELD** gave an address on the Health of the Professional Woman, which was published in full in THE LANCET of July 3rd. A discussion followed the paper.

Dr **ELEANOR LOWRY** suggested that the occupational laryngitis might be caused by: 1. Bad voice production. 2. Sinus trouble. 3. Excessive smoking.

Dr **JUSTINA WILSON**, from her experience of the National Hospital for Diseases of the Heart, confirmed the much greater incidence of rheumatic heart disease in women. Heart disease following influenza appeared to be very deadly to the heart muscle.

Dr. **MARY KIDD** agreed that vegetables rather than fruit were needed to prevent constipation. It was unfortunate that vegetables were so expensive nowadays, and also that considerable time had to be spent in cleaning and cooking them which the woman worker living alone could ill afford.

Dr **RUTH VERNEY** deplored the lack of cheap institutions to which functional nervous disease cases could be sent, since many of these cases could only be treated away from the home circumstances which might have contributed to cause the breakdown.

Dr. **MINA DOBBIE** said that practitioners ought to inquire how working women spent their leisure and holidays; often it was found that they looked after aged relatives from a sense of duty and were quite grateful to practitioners who forbade them to do so.

Dr. **E. L. ROBERTS** suggested that a possible cause of neurosis in elderly teachers was a sense of failure in not having advanced further in their profession and a lack of anything to look forward to.

Dr. **C. M. PEAKE** pointed out that the effects of the menopause might not be immediate—for example, flushings could occur long after the actual cessation of menstruation.

Dr. **A. SHEPPARD** thought that in some of the banks compulsory retiring age for women was as early as 45.

The **PRESIDENT** pointed out that the other duties outside work performed by most professional women would account for some of the excess of functional nervous disease. Neurasthenia in her opinion was always the result of emotional overstrain. There was a need for well-run nursing homes in psychological institutions where the practitioner could continue to treat the patient.—Dr **FAIRFIELD** briefly replied.

A social meeting of the Association was held at the same place on June 18th, the **PRESIDENT** in the chair. A lecture, illustrated by lantern slides, was given by Sir **JAMES BERRY** on the subject of

Greek Temples in Sicily

which Lady **BERRY** followed up by reminiscences of travel in many lands.

Sir **JAMES BERRY** dealt in the first place with the historical side of his subject sketching the main events which led to the formation of the colonies of "Magna Graeca" in Southern Italy and Sicily. He then passed on to a consideration of the architecture of Greek temples in general, their arrangement, the modifications which they underwent during the development of Greek culture, the influence of the earlier architecture of Egypt and the subsequent fate of the erections. In an enlightening series of slides showing reconstructions of temples, temples in process of building, and the quarries from which the stone was hewn, the methods employed by the Greeks in fashioning and erecting such vast stone edifices were exemplified and made clear.

Lady **BERRY** then showed a series of photographs which she had made during various holidays abroad would have a particularly bad effect upon the heart, and that the violent convulsions would put a considerable strain upon the heart Setting aside status epilepticus, however, this does not seem to be the case The cardiac condition of a patient, after having had several fits in a week, has not appeared to me to be materially worse than it was before On the other hand, that abnormalities of the circulatory system can give rise to epileptiform convulsions there can be no doubt We know, for instance, that in such conditions as Stokes-Adams's disease, where the bundle of His has been damaged, frequent epileptiform convulsions occur, as they also do in advanced cases of aortic stenosis and even in cases of arterio-sclerosis But these, of course, are not cases of genuine idiopathic epilepsy, and the question for consideration is whether, when true idiopathic epilepsy is found associated with a valvular lesion of ordinary endocarditis, the association may not be more than an accidental one

Even if there is no direct causal connexion between epilepsy and heart disease it does not follow that the two diseases are uninfluenced by one another, and, indeed, there seems reason to suppose that epilepsy, when associated with cardiac disease, exhibits some phenomena which are not quite like those of ordinary epilepsy Thus the classical onset of a fit with a cry, a fall, loss of consciousness, and convulsions is not common with the cardiac epileptics, whose attacks are characterised rather by giddiness, fits of absence of mind, and transient intellectual troubles—in a word, by psychic epilepsy The aura, too, in these cardiac cases often takes the form of palpitations, precordial pain, the feeling of a wave of blood which rises up into the head, and produces dizziness As a rule, this condition lasts longer than the ordinary epileptic aura, it develops slowly, giving the patient time to sit down, and at times the aura constitutes the whole of the attack without giving rise to convulsions or loss of consciousness The fits in cardiac cases are usually infrequent and less severe than in uncomplicated epilepsy Some of my cases have exhibited circulatory disturbances as an aura, such as palpitations, feeling of numbness in the hands, severe pain in the cardiac region, pulsation of the cervical arteries, sensation of rapid beating of the heart with the face becoming hot prior to the epileptic fit

Another feature of cardiac epilepsy is that the attacks usually occur at night, this fact has been emphasised by Lemoine,[4] who considers that in mitral cases the attacks are caused by cerebral congestion, and states that they may cease when the patient sits up in bed, whereas in aortic cases the attacks are due to cerebral anæmia and are cut short by the horizontal posture

Though I have met with a few cases of idiopathic epilepsy associated with aortic regurgitation, the most common cardiac lesion in my experience in this connexion has been mitral stenosis

It would, perhaps, seem over-fanciful to suggest that in the case above recorded the epileptic seizures were at the outset due to the previously existing mitral stenosis, yet Dr A E Russell in his most suggestive Goulstonian lecture (1905),[5] considers that there is strong evidence for an epileptic fit owing its origin to some disturbance of the circulation and regards cerebral anæmia as the fundamental factor which underlies epileptic fits Gowers, too, adduces cases[6] which present strong evidence of the influence of repeated cardiac syncope in disposing to epilepsy

THE LOSS OF ORIENTATION IN INSURED WORKMEN

ITS ECONOMIC ASPECT

By PERCY DUNN, F R C S Eng,
CONSULTING OPHTHALMIC SURGEON, WEST LONDON HOSPITAL, LATE LECTURER ON OPHTHALMOLOGY, WEST LONDON POST-GRADUATE COLLEGE.

A MAN after convalescence from the enucleation of an eye is puzzled by a symptom which is new to him. At first it amuses him, and save on inquiry he never mentions it while under examination He finds on pouring out a cup of tea that instead of the tea falling into the cup much of it falls outside Briefly, for the time being he has lost the faculty of orientation When normal binocular vision is present correct orientation is secured by the balanced action of the ocular muscles But with the loss of an eye and the change to monocular vision the disturbance of the muscular equilibrium is reflected in the temporary arrest of accurate orientation The duration of the disability is generally a question of age It usually varies between three and six weeks in young adults In older men the period is longer

As a matter of expediency no one-eyed man should be permitted to resume his employment until accurate orientation has been re-established For example, a bricklayer, unconscious of his mistake, will lay bricks out of line, if he has to ascend or descend a ladder he is liable to make a false step, with the risk of serious consequences He is aware that something is wrong with his sight, but is naturally ignorant of the cause Moreover, a man in this condition can become a positive danger to his fellow workmen, if called upon to wield a hammer for the purpose, say, of striking a rivet, the retinal image of the rivet may be displaced while striking the blow, and injury may be inflicted upon the man who is assisting him

The Position of Insurance Companies

Two points present themselves for consideration in this connexion First the economic one, secondly the position in which the insurance companies find themselves From the economic aspect the workman as long as the loss of orientation continues is confronted with an impairment of his earning capacity, apart from the loss of an eye He can no more depend upon the accuracy of his work than can his employer A bricklayer is of no use if he cannot go up or down a ladder without risk, nor is he of any use if he cannot lay bricks in line What then, under the circumstances, is the position of the insurance companies? Inevitably the weekly wage compensation must be continued until correct orientation has been restored It must be admitted that the disability has arisen indirectly as the result of an accident in the course of employment

Cases of the kind are, nevertheless, rare, as experience shows, owing to the gradual recovery from the disability But that is not all that can be said of the matter. If it should happen that the loss of orientation becomes permanent the insurance company concerned will find itself in an unenviable position Although the form vision may be adequate for resuming some occupation (and apparently county court judges are satisfied when this amounts to 6/12, with or without correction in the remaining eye), a workman may demand an exorbitant sum for the settlement of his case, and if it be refused, may take his case into court, basing his claim upon the fact that owing to the loss of his eye, a defect has developed in the other one which prevents him from defining objects clearly He emphasises that an object at first appears to him plain and distinct, but afterwards becomes blurred and unsteady Consequently he is unable to define clearly, for example, transient form, with paraplegia, clearing up in a few weeks without complications; (2) a form curable in from 18 months to two years; (3) a variety which pursues a chronic course. The prognosis in a given case depends on the following points: the condition is probably curable if the paraplegia appears early, develops rapidly, and reaches its maximum quickly, even though that be a complete paraplegia. Such cases are caused by abscess formation within the spinal canal. Those with slow development and slow progression even if incomplete, are due commonly to pachymeningitis or to vascular changes in the cord, the result of severe or prolonged compression, and are distinctly less favourable. Contrary to a widely held view, Mme. Sorrel-Dejerine considers that cure can be obtained as satisfactorily in adult as in juvenile cases, and that age is not a factor that has prognostic significance. The monograph is well documented and illustrated, and is worthy of attention on the part of both neurologist and surgeon.

Diseases of the Nervous System. By H. CAMPBELL THOMSON, M.D., F.R.C.P., Consulting Physician to the Department for Nervous Diseases and Emeritus Lecturer on Neurology, Middlesex Hospital, &c; and GEORGE RIDDOCH, M.D., F.R.C.P., Assistant Physician to the London Hospital and to the National Hospital, Queen-square. Fourth edition revised. London: Cassell and Co. 1926. Pp. 541. 16*s*.

THE fourth edition of this text-book appears with the additional name of Dr. George Riddoch as a joint author. On previous occasions we have cordially recommended its usefulness for senior students and for practitioners of medicine since it aims at marshalling the main facts of neurology in a concise and lucid manner, avoiding minutiæ and controversial topics to a large extent, and presenting the subject-matter dogmatically rather than critically. The continued demand for the book is evidence of its practical merits. In its new edition the authors have succeeded in preventing the loss of its "manual" character by removing obsolete and redundant material, so that the volume is no larger than before, although it comprises a considerable amount of new data. It will without doubt receive continuing appreciation by those for whom it is intended.

Pathologie du Cerveau et du Cervelet. (Fascicule XIX. of the Nouveau Traite de Medécine, edited by MM. G. H. ROGER, F. WIDAL, and P. J. TEISSIER.) By Various Authors. Paris: Masson et Cie. 1925. Pp. 1016. Fr. 80.

THIS handsome volume of over a thousand pages is devoted not to neuropathology alone, in the strict sense, though the pathological descriptions are voluminous and accurate, but also to the clinical and semiological sides of the topics with which it deals. These include cortical syndromes, subcortical syndromes, cerebral tumours, cerebral syphilis, vascular disorders, infantile encephalopathies, cerebellar and labyrinthine syndromes—in short, a fairly complete compendium of brain symptomatology and pathology. Among the authors are many whose names are well known beyond the limits of the neurological schools of France. Glancing through these finely illustrated pages, we realise afresh that this is the sort of thing the French do extremely well. They are masters of the clinico-anatomical method. Their knowledge is based on the collocation of clinical with pathological material, so that in their descriptions one seems to pass naturally from the former aspect to the latter, with the feeling that all has been duly correlated and explained. Nevertheless the weakness of the method is here also exemplified, if only in a negative way, for the problems of pathogenesis of symptoms are not always seriously tackled and in some instances appear to be altogether omitted. Between the commonplace clinical manifestations of athetosis, for example, and the fairly well-defined pathological lesions prone to be associated with it, lies the field of interpretation of the symptom as the expression of the action of living physiological mechanisms—a question that obviously cannot be solved by mere consideration of dead material under the microscope. This is the side of neurology that has not been so well developed by the French as by some other schools, a contention which is apparent if this volume be scanned critically. However this may be, our appreciation of the high standard of the contributions in the book is not thereby diminished: its presentment of cerebral and cerebellar syndromes is admirably lucid and comprehensive.

X RAYS AND PERIPHERAL CIRCULATION.

Die Peripheren Blutgefässe im Röntgenbild. By Dr. S. HIRSCH, Senior Int. Physician, Sandhof, Frankfurt a.M. Frankfurt a.M.: Kein and Nemnich. 1924. Pp. 72. M.6.90.

THE possibility of demonstrating the peripheral circulation in the living subject by opaque injections into veins has aroused much interest among radiologists, but the work has not been followed up in this country. This interesting monograph gives an account of the technique and possibilities of the method, based on the author's original experiments. In over a hundred cases a few c.cm. of a 10 per cent. solution of strontium bromide have been injected into living subjects without ill effect. The method is only applicable to limbs, in which the circulation can be stopped by compression. The work is in the experimental stage and has not as yet been turned to practical account in the study of disease, but the photographs convincingly demonstrate its possibilities. The monograph also contains detailed information on injection masses and solutions suitable for X ray investigation of anatomical specimens and for the study of the circulation of animals by the injection of opaque substances. This information should be of value to anatomists and experimental physiologists and pathologists.

OVERPOPULATION.

Theory and Statistics. By P. SARGANT FLORENCE. London: Kegan Paul. 1926. Pp. 66. 2*s.* 6*d.*

THIS little book, which is a recent addition to the "Psyche" miniature series, is a restatement—based upon a simultaneous consideration of history, theory, and statistics in the light of the economic developments and new social practices of the last century—of the position of Malthus. The events of the last hundred years have been held by many to refute this writer's more salient arguments. This refutation, Mr. Florence contends, results from a misrepresentation of what, in effect, Malthus, in his later writings especially, actually said, and upon a dissociation of historical, theoretical, and statistical lines of argument which, in Malthus's writings, were combined. Malthus's three cardinal propositions are distinctly enunciated, and attention is directed to misinterpretations of his views arising from failure to differentiate the last two of these propositions.

Origins of variation in the birth-rate are then considered, and it is argued that the recent fall in the birth-rate manifest among the well-to-do is attributable to the introduction of contraceptive methods and not to cyclical variations in fecundity such as were observed over short-term periods in the second half of the last century. Mr. Florence further argues that the *sustained* magnitude of our post-war unemployment figures expresses more than a cyclical variation in trade, such as the one that appeared so ephemerally in 1879. It would appear, in fact, to represent a growing margin of unemployed over and above these cyclical variations, which may testify to a more chronic state of overpopulation. The book ends with an attack on the view that we are justified in adopting a "laissez-faire" attitude towards problems of population, certain recent pronouncements notwithstanding. If we choose to say that the growth of a given population

Artificial Sunlight and Its Therapeutic Uses. By FRANCIS HOWARD HUMPHRIS, M.D. Brux., F.R.C.P. Edin., Hon. Consulting X Ray Physician to the American Hospital in London and to Christ's Hospital. London: Humphrey Milford, Oxford University Press. 1926. Pp. 236+xx. 8s. 6d.

Les Rayons Ultra-Violets en Thérapeutique. By Dr. SAIDMAN. Paris: Octave Doin. 1925. Pp. 580. Fr.65.

THE third edition of Dr. Humphris's book on the therapeutic uses of artificial sunlight has been enriched by numerous illustrations, the most attractive of which is the one forming the frontispiece and which represents Akhnaton with his wife Nefertiti at worship in the radiance of the beneficent sun. The volume contains a great deal of information which can be put to immediate use by those wishing to carry out this form of therapy. The author is more convincing when he treats of the practical application of artificial light therapy than when he enters upon biophysical ground. We can hardly expect agreement yet upon the essential processes set going by ultra-violet radiation. Dr. Humphris tells us that the calcium content of the blood is increased by exposure to these rays; but the data given on p. 69 are hardly sufficient to support this statement. They show the percentage change of calcium of the serum of rachitic children before and after exposure to light in seven cases. In two there is a fall of the calcium content and in three others the increases are only 2, 5½, and 5½ per cent. respectively. If it be a fact, it should be possible to find more convincing evidence of it. Exactly what are the main changes brought about time and experimental work will show; Dr. Saidman, for one, will have none of the usually ascribed chemical actions as even mainly contributory. For him and others of his school the photo-electrical effect of the rays is all sufficient. With this well-known phenomenon in mind, he would be bold who would yet claim to have found any rational explanation of the remarkable therapeutic changes brought about by ultra-violet rays which are enumerated by Dr. Humphris on p. 80 of this edition. The book retains the useful features on which we have previously commented and will continue to be popular among the swiftly increasing group of practitioners who have added artificial light apparatus to their armamentarium.

Dr. Saidman's book is divided into three parts. The first is concerned with technical matters and contains a good account of the sources of ultra-violet rays, how they are used, and what precautions are necessary in their medical application. The second part is devoted to the physiological action of these rays and, as a prelude to this study, some account is given of the process of absorption of the rays by different media and the phenomena of photo-electricity. This second section of the book gives one of the best accounts which we have seen of the facts which have so far been obtained upon the physiological reactions consequent upon irradiation by light and ultra-violet rays. The third section of the book is devoted to therapy, and is divided into three parts dealing with the use of ultra-violet rays in surgery, in medicine, and in diseases of children. Then follow an extensive bibliography and a series of spectra relating to subjects discussed in the text.

We think it unfortunate that the author pins his faith so exclusively upon a photo-electric explanation of all the complex effects in living things which follow upon ultra-violet exposure. No doubt it plays some part in some of the processes, but there is so little direct experimental work in support of the theory that it would seem better to keep an open mind on the subject, rather than to reject summarily other facts which may bear upon the vital processes which are quickened so amazingly by judicious exposure to the rays. On the whole, however, we can recommend the book to readers who wish to extend their knowledge of the subject.

INDIAN HYGIENE AND PUBLIC HEALTH.

By Lieut.-Colonel C. L. DUNN, D.P.H., I.M.S., Director of Public Health, United Provinces, and RAI BAHADUR D. D. PANDYA, D.P.H., Director of Provincial Hygiene Institute, United Provinces. Calcutta and London: Butterworth and Co., Ltd. 1925. Pp. 679. 22s.

THIS volume is intended to serve as a text-book for candidates for diplomas in public health in India and especially for those studying in the United Provinces. Although its matter is definitely related to the public health problems of India, its form follows closely the English text-books. Chapters are devoted to water supplies, ventilation, disposal of refuse and excreta, building sites, food, communicable diseases, disinfection, housing and town-planning, personal hygiene, school hygiene, meteorology, vital statistics, and sanitary law. Six appendices contain physical data and other facts of practical utility to the sanitarian. There are numerous and elaborate illustrations, and the authors have spared no pains in supplying their readers with information.

The publication of this book and another recently reviewed in these columns may be taken as a measure of present-day public health activity in India. It may be necessary to feed the mind of the student trained in India with potted knowledge—probably no one knows this better than Colonel Dunn or his collaborator—but we think the authors sometimes fail by trying to convey too much, thus not leaving space which might well have been employed otherwise. For instance, the time-honoured calculations of respiratory impurity and standards of ventilation might have been omitted in the light of modern work and, instead, some mention made of the kata thermometer. The absence of reference to accessory food substances is unfortunate, and the description of the causation of beri-beri and pellagra is inadequate. Indeed, the physiological outlook which is gradually removing the hygienists from the thraldom of the sanitary engineer is not markedly exhibited by the authors of this book. We look in vain, too, for the elucidation of such questions as the reputed prevalence of non-pulmonary tuberculosis among some groups of Indians whose milk is mainly derived from buffaloes. Nothing is said as to the prevalence of tubercle in the latter.

While this volume is disappointing in the respects indicated, it contains a mass of facts that will be of great value to the administrator, for they are well put together and indexed, while the work is produced at a very reasonable price.

NEUROLOGY.

Contribution à l'Étude des Paraplegies Pottiques. Essai sur l'Évolution et le Prognostic; basé sur 40 Observations Personelles. By Mme. le Dr. SORREL-DEJERINE, Ancien Interne des Hôpitaux de Paris. Paris: Masson et Cie. 1926. With 97 illustrations. Pp. 399. Fr.40.

Pott's disease of the spine is a condition which is possibly not so frequent as it used to be; it is a clinical "uncommonplace," but its most suitable treatment still remains sub judice. Its varieties and its pathology, in children and in adults, are curiously variable, as are its course and termination. Some cases are favourable from the outset, others the reverse. The daughter of the late Prof. Dejerine, impressed by these facts, has made in the book under review a noteworthy contribution to the subject, based on abundant clinico-pathological material, and has reached conclusions which may be summarised as follows. There are three chief varieties: (1) a

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives health statistics for 1925 from six districts of varying type A high birth-rate, usual in colliery districts. will be noted in Doncaster and may be compared with that of Swinton, on the Lancashire coal-field, where. in addition to 3710 males engaged in mining and allied occupations, there are 3948 textile workers (877 males and 3071 females)

Name of district.	Estimated mid-year population (R. G.).	Birth rate.	Death-rates per 1000 of the population. All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Death-rates per 1000 births. Infant mortality	Maternal mort. from childbirth.

Sunderland

Owing to the recent death of Dr. H. Renney, Dr Eustace Thorpe. temporary medical officer of health submits the annual report, which was revised by Dr Renney before his death

The water-supply of Sunderland is derived from deep wells in the magnesian limestone During 1925 bacteriological examination resulted in the finding of *B. coli*, in 100 c cm , in more than 40 per cent of 212 samples examined. The comment is made that its presence " is no doubt due to the deposit of manure, droppings of cattle and sheep, and of night soil used by the farmers as a land fertiliser The bacilli. washed out of these deposits by the rainfall, are carried through the subsoil and thence by cracks in the clay and fissures in the limestone to the wells sunk in these strata " Sunderland is now almost a water-carriage town, the 1226 remaining conservancy closets being of the small covered-in type commonly known as ash closets The housing shortage is still urgent. and innumerable instances are known " of families of seven or more living in one room and of five or more of such families living in one house with conveniences for one family only " A further 3000 houses are required, all of a working-class type, and representations have been made with regard to three unhealthy areas Out of 106 samples of milk examined five were found to contain living tubercle bacilli Four of the farms situated outside the borough were visited by the veterinary surgeon and in each case a written undertaking was received from the farmer that he would not send milk from the suspicious cows into the borough for sale. In one case the county M O H was notified At the fifth farm situated within the borough three suspicious cows were found. and one was slaughtered, compensation being paid Three cases of small-pox were notified, and 31 cases of encephalitis lethargica in 27 of which the diagnosis was confirmed During the year 11 mothers received antenatal treatment for syphilis and the eight infants born to them were quite healthy Ultra violet rays have been used at the infirmary for rickets, but it is felt that this treatment can only be carried out satisfactory at the centres owing to the difficulty of ensuring regular attendance. In March a scheme for antenatal visitation by the midwives was begun on the basis of a payment of 2s. per case for satisfactory work. During the year 66 cases of ophthalmia neonatorum were notified; one baby became blind and two had one eye damaged. Appreciation is expressed of the Eye Infirmary's treatment of these cases but unfortunately it has not yet been possible to arrange for a ward to which such babies can be admitted as in-patients At the municipal hospitals a bed isolation ward has been successfully used for treating simultaneously many different diseases without the occurrence of cross-infection

Stockport.

Dr A G. Jenner died last October and the deputy medical officer of health. Dr H. Richmond, submits the report The number of new houses erected was 405, as compared with 241 in the previous year, and at the end of the year there were 204 in course of erection Nevertheless there is still not enough housing accommodation of the smaller type Early in the year an arrangement was made with the Stockport Infirmary for the treatment of infantile paralysis, tuberculous bones and joints, rickets, congenital defects. and injuries The orthopædic centre formed is in charge of Mr. E S. Brentnall, and a trained masseuse is in attendance During the last six months of the year 48 cases were treated, 24 X ray examinations were made, and eight cases were admitted as in-patients There were also 151 attendances for massage and 387 for medical exercises. The cost of surgical appliances in connexion with the scheme is borne by the estate of the late Miss Maria Leigh. The arrangement has still to receive the approval of the Ministry of Health. It is remarked that of 130 fatal cases of tuberculosis, 20 had not been notified at the time of death.

Bootle.

Dr. F. T H. Wood reports that an apparatus for ultra-violet light treatment was installed at Linacre Isolation Hospital in October, 1925 Antenatal clinics have established themselves in the public mind and during 1925 about 1 in 4 of the expectant mothers came for examination and advice. The close association between the clinics and the maternity home. and through the consulting gynæcologist, with the Liverpool special hospitals, adds much to their value. During the year 128 patients were admitted to the maternity home. There were no maternal deaths, three children were stillborn and three died of debility within ten days One case of ophthalmia neonatorum occurred which was transferred to the Liverpool Eye Hospital and there cured All the mothers left the institution breast-feeding their babies except three, who had mastitis As regards the health of infants generally, Dr. Wood points out that, although intestinal diseases have almost disappeared as a cause of death, no real improvement can be recorded in respiratory diseases, and that the deaths of infants in the first month remain as numerous as they were 20 or 30 years ago He gives a table showing that the neonatal death-rates during the last four quinquennia were 36·7, 41·5 31·5 and 34·6 per 1000 births respectively.

The milk-supply is unsatisfactory and " remains demonstrably dirty,' and the general public is unwilling to encourage improvement by recognising that difference in quality implies difference in price. Out of 28 samples examined. one reached the standard of Certified milk. two of Grade A milk, and one half were grossly contaminated Two of the 28 contained tubercle bacilli In July the isolation hospital decided to purchase Certified milk and similar action was urged upon the management of the Bootle Borough Hospital A number of local distributors have begun to supply bottled milk without complying with any of the regulations for designated milk. This milk is the ordinary unsatisfactory milk and the imperfect arrangements for sterilising the bottles have probably is a "biologically self-regulating process," as has of late been authoritatively stated, we are not to suppose that the actual mode of the self-regulation is either immaterial or beyond our control Deliberate regulation of births by human beings is capable of entering into the process as intimately as does the fortuitous multiplication occurring in communities that suffer from high birth- and death-rates

Though short, this book is closely written and closely reasoned At times, especially in the second chapter, the literary style is too involved to make easy reading, and in one sentence in the middle of page 10 sustained contemplation has failed to reveal a meaning. But the book contains some interesting statistics, and its conclusion that population cannot safely be ignored, in the belief that it will regulate itself to our convenience, is important

EAR, NOSE, AND THROAT THERAPY

Handbuch der Hals-Nasen-Ohren-Heilkunde Edited by A. DENKER and O KAHLER Second volume Diseases of the Air Passages and Mouth, II. Berlin · Julius Springer; Munich · J F. Bergmann 1926 Pp 1068

THIS is the second volume of a very large text-book which, when completed, will consist of nine volumes The first five are to deal with the mouth cavity and upper air passages, and the rest with the ear The first volume, which has already received notice in these columns, was devoted to the anatomy, histology, physiology, and methods of examination of the upper air passages The volume under review is concerned with ætiology and pathology, and in the first 353 pages these subjects are considered generally This is the least satisfactory part of the book, being composed largely of vague generalisations Such factors as climate, age, or injury could be considered under the separate diseases of the parts in question more usefully than by a discussion of their effects on the air passages in general, and the same criticism applies to the chapters on general symptomatology The section on general therapy is far more useful, and includes accounts of general and of local anæsthesia Methods of local therapy for the nose and throat are well described, but it is not clear why the operation of tracheotomy should be placed here rather than in a later volume with other operations on the larynx and trachea After these generalities we reach the beginning of the descriptions of special diseases which will occupy the rest of the five volumes dealing with the upper air passages First come malformations of the nose, throat, including palate, lips and tongue, larynx and trachea, this chapter describes, in addition to the well-known deformities, some interesting cases of rare malformations The remainder of the volume is occupied with the nasal septum, acute and chronic rhinitis, and diseases of the nasal accessory sinuses It will be noticed that the work is arranged on a general, not a regional classification, deformities of the nose, throat, and larynx come into this volume, foreign bodies in all these regions into Vol III, tuberculosis in Vol IV, and tumours in Vol V In the present volume the various chapters are in the hands of acknowledged authorities; they are well written, well illustrated where illustrations are required, and are thorough and complete The second volume is a worthy companion to the first, and the two make a good beginning to what seems likely to be a great work

---

DISEASES OF THE MOUTH, AND OTHER REGIONS

Non-Surgical Treatment of Diseases of the Mouth, Throat, Nose, Ear, and Eye By THOMAS H ODENEAL, M D, Otologist, Rhinologist, Laryngologist, and Ophthalmologist to the Beverly Hospital, Massachusetts London. H K. Lewis and Co. 1926 Pp 428 17*s*

THIS is an attempt to describe the diagnosis and treatment of the diseases of all the special regions enumerated in the title in such a way as to be "of material assistance to the young specialist and to the general practitioner" Unfortunately, the attempt cannot be said to have succeeded, though there is plenty of sound advice scattered through these pages, and though the dogmatic tone of the author is proper in so concise a book, the treatment throughout is described in too short and summary a manner to be of any real value to the general practitioner, still less to the young specialist To take one instance out of very many, it is not worth while to mention salivary calculi at all when the only thing said is that "calculi in these ducts or glands give the patient a sense of a foreign body or a lump in the floor of the mouth", nothing is said about their treatment. If the short notes on rare conditions, such as Thornwald's disease and laryngocele, had been omitted, more space might have been found for discussion of the commoner and more important affections The writing might have been more carefully revised; the recommendation of 30 per cent carbolic acid in glycerine as ear-drops, which is mentioned twice, is surely intended for 30 gr to the ounce, for this purpose carbolic acid is seldom used at more than the latter concentration

---

BODILY FUNCTION FOR THE LAYMAN

Sex and the Young Pp. 190. 6*s* 6*d* *The Human Body and its Functions* Pp 224 6*s* 6*d*. Both by MARIE C STOPES, D Sc London Gill Publishing Co 1926

THOSE who are not irritated by Mrs Stopes's manner of imparting knowledge will find a great deal of good sympathetic common sense in her contribution to the question of how to teach children about sex It is a matter which has been much discussed in recent years and extravagant opinions one way and the other have not been wanting A while ago there was a rather widespread idea that children ought to be taught about sex as such Practical experience has, we believe, led some of the advocates of direct instruction to change their minds, and Mrs Stopes takes a strong line against this special treatment of a subject which does not occupy the predominant place in the consciousness of children that it is apt to have in adults Sex, she says, should not be taught, children should rather learn it in the ordinary course of learning the elementary anatomy and physiology which she would have everyone know about at an early age, and they will regard it as just as commonplace—or just as miraculous—as the heart or the bowels To provide her ideal introduction to the functions of the body, she has written the Human Body and its Functions as a companion volume All of which is as sane and reasonable as her remarks on the real necessity of allowing school-children plenty of time in the morning to get into a regular habit of opening their bowels, or the disadvantage of making a boy conspicuous by a complete rather than a partial circumcision, or the desirability of having a larger proportion of married teachers and various other similar topics, some of them of the beastly kind which do not often get such frank treatment We have less sympathy with her suggestion that THE LANCET should be taken in the school staff library, nor are Bayliss's "General Physiology" or Marshall's "Physiology of Reproduction" quite the books to recommend to relatively untrained lay people

The Human Body and its Functions contains 22 chapters wherein more attention is paid to function than to details of structure, and function of the systems and organs of the body are discussed in sufficient detail Some would prefer a more objective account to be given to children and young people, without comments pointing the moral—for example, that it is "wickedly cruel to leave a baby in a perambulator with the hood over it in such a way that the glare of the sky goes straight into the baby's eyes" Others may welcome a book which combines instruction in anatomy, physiology, principles of hygiene, and with hints as to conduct. The book is well produced and the illustrations are clear the year there has been a slight rise in the malnutrition figure, from 5.9 to 6.1 per cent. The assessment of malnutrition, however, is so dependent on the personal factor that changes in the examining officer will vary the figure considerably. Another important factor mentioned is over-fatigue but this, again, is difficult to estimate and even medical opinion is divided as to the amount of sleep required in various ages. To allow a child to have its sleep out is perhaps best, but the condition of many homes and streets makes it impossible for children to get enough sleep. At the aural clinic ionisation is still carried out with very successful results. At the throat clinic, after operation for tonsils and adenoids, detailed instructions are given, and children practise breathing exercises at the remedial exercises clinic. There are still no special schools for the educable feeble-minded in the borough.

Leeds.

Dr Algernon Wear presents an account of the school medical services, and to this is appended the report of the organiser of physical education and that of the chief inspector of the employment of children; the whole is an excellent survey of the work for child welfare. The ascertainment of defects appears to be very thorough and the children in special schools are inspected every two years. For treatment there is a good provision of clinics though the rapid increase of work calls for enlargement and extension of many of them. There has been a substantial decrease in ringworm and scabies cases, but a marked rise in malnutrition, largely due to unemployment in the area. Open-air school accommodation is very limited, but a school for pre tuberculous children is to be opened this year. Dr Wear alludes to the problem of the physically defective children who are also mentally retarded. Such retardation is, in fact, much more frequent than is generally supposed, it varies in degree from mere backwardness to the severe mental defect sometimes found with cerebral paralysis. Children who are severely crippled and only slightly subnormal can be dealt with, as Dr Wear says by putting them in an appropriate class in a special physical defective school. Those who are actually mentally defective present greater difficulty, and from the purely economic standpoint the result of any kind of educational treatment is seldom proportionate to the cost, since few of them are ever made even approximately self-supporting. Dr Wear recognises the need for manual training for elder mentally defective boys; this would afford better prospects of satisfactory and lasting employment. Eighty per cent. of the children in the schools were inspected by the dentists and 44.6 per cent. of those requiring treatment received it. Every child in the nursery schools was examined and an average of 4.6 defects was found in each infant. Competitions for healthy children of various ages were held and were well attended. Valuable research is being conducted on the development or aggravation of defective vision and squint. The scheme is a continuous one and the conclusions are not yet available but its results should, as Dr Wear says, be far-reaching and of the greatest importance to the study of the ophthalmology of the child.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 26TH, 1926

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox 165 (last week 150); scarlet fever 1355; diphtheria, 858; enteric fever, 78; pneumonia 587; puerperal fever, 36; cerebro-spinal fever, 10; acute poliomyelitis 10; encephalitis lethargica 17; dysentery 16; ophthalmia neonatorum, 131. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 3 (0) deaths from enteric fever, 26 (3) from measles, 4 (2) from scarlet fever, 26 (4) from whooping-cough, 38 (11) from diphtheria, 54 (13) from diarrhœa and enteritis under two years of age, and 37 (7) from influenza. The figures in parentheses are those for London itself.

MENTAL HOSPITAL REPORTS

THE *Glasgow Royal Asylum* had an average of 525 patients resident during 1925, and nearly 50 per cent. of the year's admissions were voluntary boarders. The physician-superintendent draws attention to the fact that only one case of general paralysis was received, which coincides with the general impression that this condition is less frequently encountered than formerly. The death-rate was 8 per cent. The number of patients at the psychiatric out-patient clinic at the Western Infirmary is steadily increasing. The occupational therapy of this institution is well known and a new pavilion has been opened. The central hall is used as an art room for quiet occupations, relieving the congestion of the class-rooms and keeping an atmosphere of quiet in the hall that often induces excited patients to settle to work. A successful sale of work and a Christmas party were organised. Butter has been substituted for margarine and the visiting commissioners note that every effort is made to approximate the dietary to the idiosyncrasies and home conditions of individual patients. The seaside home at Skelmorlie continues to be a useful and popular adjunct to the main buildings. The dentist removed 341 teeth during the year, mostly under local anæsthesia and stopped 32 more. Difficulties in treating mental cases might be anticipated, but have not in fact proved a serious bar to his work.

The *Cheshire County Mental Hospital* at *Parkside* was overcrowded with patients at the end of the year, but the excess has been partly relieved by the transference of some cases to workhouses. The death-rate was the lowest for 25 years (5.61 per cent.); and the recovery-rate showed an advance on that of the previous year, reaching 31 per cent. Post-mortem examinations were held on 63 out of the 70 patients who died during the year. General paralysis and arterio-sclerosis accounted for more than half the deaths. There was some mild influenza and eight cases of dysentery, but no other epidemic disease. 64.7 per cent. of the male patients and 61.9 per cent. of the females were usefully employed last year, and an instructor for the male side has been appointed in addition to the instruction mistress. Eighty-three cases have been taught some form of handicraft, and a gymnasium has been added to the recreation department. Parole has been granted to about 200 patients. Special facilities are available for treating recent cases. Treatment and clinical rooms and verandahs are attached to the admission wards, and the visiting commissioner speaks of the treatment rooms as "models of their kind." Each contains continuous needle and shower baths, a radiant heat bath and a massage couch, and is staffed by skilled nurses. Ultra-violet radiation plant has also been installed, and the medical superintendent reports that the good results following its use have included marked increase of weight, muscular activity and cheerfulness, with slight decrease in blood pressure. Manic-depressive cases have responded the most readily, and mild cases of melancholia and delusional insanity with irritability have also benefited. The treatment is contra-indicated in melancholia and seems inactive in dementia præcox. A good deal of valuable research work has been carried out in the laboratory, including observations on blood pressure in varying mental states, the sudorific reactions of the skin, the value of ovarian extract in the insanities of child-bearing and the intestinal flora of patients with diarrhœa. Seven more nurses obtained their final certificates during the year, and it is welcome news that the superintendent is finding that a better and keener type of probationer is now entering the service. A sister tutor has been appointed. General paralytics have been treated with malaria, and two cases have been discharged and continue well, while seven appear distinctly improved. We characterised this institution last year as "one of the most up-to-date and progressive in the kingdom" and it is clear that the staff are not resting on their laurels rather increased than decreased the chances of contamination In confirmation, it is pointed out that the dirtiest of the 28 samples examined was a bottled milk of this type and that five other samples of such bottled milk occupied very unfavourable positions in the list Of 49 milk samples taken at the railway stations no less than 11 contained added water, varying in amount from 2 5 to 29 per cent

The Schick test has been used for scarlet fever admissions to hospital It was found that 15 out of 19 children under 5 gave positive reactions; 18 out of 43 at the age-period 5 to 10, 5 out of 16 at ages 10 to 15, 2 out of 4 at age-period 15 to 20, and 1 out of 4 at ages over 20. Only one of seven new probationer nurses gave a positive reaction, and she was immunised One midwife was reported to the Central Midwives Board during the year for failing to notify a case of ophthalmia neonatorum, and her name was removed from the roll The case in question came under treatment when 15 days old, and the results were very serious Some improvement in housing has been brought about by the erection during the year of 98 houses of site No 1 There is still much need for more municipal building, for there is much overcrowding

Doncaster R.D.

Dr A B Dunne laments the spoiling of his beautiful district by industrial invasion with its pillars of smoke by day, but no doubt derives satisfaction from the fact that the industrial communities are the best housed in it Out of 37 parishes about 6 have been converted from agricultural to industrial communities When the projected colliery in Awkley parish has been sunk the inner ring of collieries surrounding Doncaster will be complete "The standard of living is high and there is an appearance of well-being and prosperity about the colliery villages" Since the war a large glass industry has been established at the old village of Kirksandall, up to which point the river Don is tidal As predicted in 1911 by the late Mr W H Pickering, H M Inspector of Mines, districts in the Dearne Valley and in Askern have been flooded by subsidence During the last five years the colliery companies and glass manufacturers have erected over 2000 excellent houses on town-planning lines The change over from rural conditions has meant a tremendous influx of children for whose accommodation large schools on modern lines have been built The industrialised districts are provided with modern sewage disposal works There is no maternity hospital in the district, but difficult cases have until now received attention at the Doncaster Royal Infirmary Recently the county council have arranged for the admission of special cases to a private maternity home There are sufficient midwives, but they are somewhat unevenly distributed Dr Dunne reports that "a healthy public opinion regarding child welfare is being formed" During the last five years there have been 13 cases of enteric fever with 3 deaths, 16 cases of puerperal fever with 3 deaths, 6 cases of ophthalmia neonatorum with 2 deaths and no impairment of vision among survivors, and 2 cases of encephalitis lethargica with 1 death

Swinton and Pendlebury U D

Dr H C Mulholland reports a gradual improvement in the milk-supply of the district, but also mentions that some milk sold in bottles is no better than any other He looks to public opinion to secure a higher standard of cleanliness in milk and food matters Flooding of part of the area has occurred through the subsidence of sewers from mining operations, and is being dealt with by reconstruction of the sewers A nuisance has been caused by the refuse tip and a salvage plant is to be erected to deal with all the refuse In the last quarter of the year there was an outbreak of typhoid fever, consisting of six cases in one house The origin was a missed case, a man of dirty habits, but it could not be ascertained how he had contracted the disease Housing shortage is considerable, and 51 cases of gross overcrowding were reported during the year The number of persons living more than two to a room increased from 2344 in 1911 to 3165 in 1921 Since 1921 the Council has built 230 houses under the Addison scheme and 208 have been put up by private enterprise under the subsidy scheme Negotiations are in progress for the purchase of two estates, of 16½ and 63 acres, for further housing Unhealthy areas, including 274 houses and housing 1428 persons, are waiting to be dealt with Dr Mulholland insists on the need for reinspection of houses which have been rendered fit, in order to prevent damage by careless tenants, as in certain cases renovation has had to be repeated within two years

Stafford.

Dr J T Macnab reports that two milk producers have been induced to supply Grade A milk and that the corporation has supported them by purchasing this milk for the child welfare centre and the isolation hospital Housing conditions have been improved but Dr Macnab estimates that another 200 houses are needed at present The corporation has purchased more land and contemplates the erection of 140 houses thereon There are still houses in the borough with no sinks and without an inside water-supply A matter requiring attention is the abolition of the slop-water closets Two men are kept constantly employed in dealing with stoppages in them They number 2283

SCHOOL MEDICAL SERVICE

IN the following table the figures given in the reports from Gillingham, Bootle, and Leeds are set out

Name of town	No on roll.	Av elem school attendance	No of routine children examined	No of special examinations and re inspections	Percentage of children found on routine examination requiring treatment *
Gillingham	7,440	6,775	2,498	1,306	16·0
Bootle	12,176	10,887	3,831	11,405	33 3

* Excluding uncleanliness and dental defects. † Not given

Gillingham

Dr W. A. Muir, M O H and S M O, in introducing his report, discusses the prevention of mental deficiency and briefly states his views that sterilisation in selected cases, combined with segregation, would go far towards reducing the number of cases Whether this is true or not there is little doubt that many of the feeble-minded are enabled to become wage-earners by suitable training in special schools and institutions Such accommodation is far from adequate throughout the country, and in Gillingham alone there are 24 known mentally defective children in elementary schools The fight against uncleanliness continues to absorb much of the time and energy of the staff, and Dr Muir sounds a warning note about the still high percentage of verminous children (16 per cent) The evil effects of dust, both from the economic and the medical point of view, are well known, and many areas have had good results from applying dust-allaying preparations in their schools Such an experiment is being tried in three of the Gillingham schools An orthopædic scheme is under consideration and may soon be working Open-air classes are held in a few schools The net cost to the ratepayers for the school medical service during 1925 was ¾*d* in the £

Bootle

Dr. F T H Wood presents his usual interesting and well-arranged report He is fortunate in his committee and draws attention to the great help he has received from them The cost per child was about 4s 9*d* gross and 2s 4*d* net, this being a decimal part of a penny rate (1 3 gross and 0 65 net) During

The Services.

ROYAL AIR FORCE MEDICAL BRANCH

NEW PAY AND CONDITIONS.

As was announced in THE LANCET last week, improvements have been made in the conditions of service and emoluments of medical officers of the Royal Air Force with the intention of attracting into the Service the best type of medical man The duties of a medical officer in the Air Force include not only the prevention and treatment of ordinary diseases and of those to which the personnel of the fighting services may be liable, but the special study of the mental and physical stresses on the aviator

Entry being by means of a short service commission for three years, extensible to five, the officer is not committed to a permanent career Permanent commissions are granted by selection from those holding short service commissions, and every entrant has a 50 per cent chance of permanency Short service officers passing to the reserve after five years will receive an increased gratuity of £700, but the gratuity after three years' service remains at £350

Increase of Pay

Increases of pay of from 2s. to 11s a day have been granted in all ranks above Flight Lieutenant and the scale in force from July 1st, 1926, will be seen from the following table The rates shown in the first column are "standard" and are liable to the extent of 20 per cent. to periodic variation according to the cost of living The current rates are shown in the second column, and in the third the total yearly emoluments at current, rates if allowances are drawn in cash in lieu of provision being made in kind The cash allowances included are at current home rates for unmarried officers. Married officers over 30 years of age receive higher allowances

Rank	"Standard" rate of pay per diem			Current rate of pay per diem			Current rate of pay and allowances per annum
	£	s	d	£	s	d	£
Flying Officer	1	4	0	1	2	6	557
Flight Lieutenant	1	6	0	1	4	6	608
Flight Lieutenant after two years in the substantive rank	1	8	0	1	6	6	645
Flight Lieutenant after four years in the substantive rank	1	10	0	1	8	4	678
Squadron Leader	1	14	0	1	12	2	760
Squadron Leader after two years in the substantive rank	1	18	0	1	15	10	827
Squadron Leader after four years in the substantive rank	2	0	0	1	17	10	864
Squadron Leader after six years in the substantive rank	2	4	0	2	1	6	931
Squadron Leader after eight years in the substantive rank	2	8	0	2	5	4	1001
Squadron Leader after ten years in the substantive rank	2	10	0	2	7	4	1037
Wing Commander	2	15	0	2	12	0	1133
Wing Commander after two years in the substantive rank	2	17	0	2	13	10	1166
Wing Commander after four years in the substantive rank	3	3	0	2	19	6	1270
Group Captain	3	10	0	3	6	2	1463
Air Commodore	4	0	0	3	15	8	1691
Air Vice-Marshal	5	0	0	4	14	6	2100

Promotion to Flight Lieutenant occurs after two years' satisfactory service and to Squadron Leader after ten years' service, reducible to eight years in exceptional cases Promotion above Squadron Leader is by selection, subject to minimum periods of service The Director of Medical Services, if as at present an Air Vice-Marshal, will receive the pay and allowances of his rank.

Retiring Allowances to Permanent Officers.

The gratuities issuable to permanent officers have been increased to £1500 after 10 years' service and £2500 after 15 years' service After 20 years' qualifying service officers are eligible for retired pay, the amount depending on age and length of service and in the case of senior officers on rank. The maximum rates of retired pay are, subject to certain conditions, as follows, the rates for Air Commodores and Air Vice-Marshals being new.—

Rank	"Standard" maximum rate	Current maximum rate	
	£	£	s
Air Vice Marshal	1010	954	10
Air Commodore	950	898	0
Group Captain	900	850	10
Wing Commander	600	567	0
Squadron Leader	500	472	10

Various Improved Conditions

Officers who have held resident appointments in recognised civil hospitals for not less than one year (of which half may be spent as non-residents) will be antedated one year for purposes of seniority promotion, retired pay, and retiring gratuity, the valuable experience provided by hospital appointments being thus recognised Every officer on entry will receive eight weeks' special instruction in the medical problems connected with flying and other Air Force duties, while with a view to enable the officer to take general or special courses, whether at civil or service medical schools, study leave up to nine months in all will be allowed during the first 16 years of service The promise should be noticed that as far as possible officers will be allowed to take such study leave when convenient to themselves and to choose their subjects and places of study

The Nursing Service

The Air Ministry also announce a revised scheme of emoluments, including pay and retired pay, for members of Princess Mary's Royal Air Force Nursing Service A permanent member of the Service will now be permitted to retire with a gratuity of £250 after ten years' service and £400 after 15 years

ROYAL NAVAL MEDICAL SERVICE

Surg Capts R J MacKeown and F H Nimmo to be Surg Rear-Admirals, and are placed on the Retd List at their own request

Surg Capt R StG S Bond to be Surg Rear-Admiral

Surg Lt. C H Savory to be Surg Lt-Comdr

ROYAL ARMY MEDICAL CORPS

Col F F Carroll, half pay list, retires on retd pay

Maj R G H Tate retires on retd pay, and is granted the rank of Lt-Col

J W Kendall to be temp Lt

MILITIA

Capt H C Bazett to be Maj

ROYAL AIR FORCE

Wing Comdr A W Iredell to be Group Capt

Squad Leaders W A S Duck and A E Panter to be Wing Comdrs

Flight Lt. H E H Tracy to be Hon Squad Leader

Flying Officer H W Corner is promoted to the rank of Flight Lt.

NORTH PERSIAN FORCES MEMORIAL MEDAL —Dr W Corner, O B E, Iraq Health Service, has been awarded the North Persian Forces Memorial Medal for the year 1925 for his paper on Malaria in the Kirkuk Division of Northern Mesopotamia during 1923, published in the *Transactions* of the Royal Society of Tropical Medicine and Hygiene (1925, vol. xix, Nos 1 and 2) This is the third award of the medal, which is awarded annually for the best paper on tropical medicine or hygiene published in any journal during the preceding 12 months by any medical officer, of under 12 years' service, of the Royal Navy, Royal Army Medical Corps, Royal Air Force, Indian Medical Service, or of the Colonial Medical Service, provided that a paper judged to be of sufficient merit has appeared

THE LANCET.

LONDON: SATURDAY, JULY 10, 1926.

THE STANDARDISATION OF INSULIN.

THE discovery in the laboratory of some new therapeutic agent at once opens up a whole series of important problems both from the clinical and the industrial point of view The control of a powerfully active substance when made by one laboratory on a small scale and tried on a few patients is a relatively small matter owing to the few persons engaged in the whole process As soon however, as the substance is manufactured on a large scale and is handed out to the world at large difficulties begin to creep in. In the first place, there is the question of the transference of a small scale operation to a large scale. This is very often a matter of great difficulty, and the efficiency depends on the skill and organising power of the manufacturers. The standardisation however, is a matter which can only be undertaken by those persons who have experience in biological tests. If all the preparations made by different manufacturers are to be of the same strength a central controlling body is a necessity. If all preparations are not of a standard strength disastrous results may occur when patients are treated with material emanating from different firms The Medical Research Council in England early assumed control of the standardisation of insulin in this country, and evolved a highly efficient organisation whereby every batch of insulin bought on the English market had to undergo standardisation. It is obvious that if this uniformity is desirable for any one country it is also desirable for the world at large, and the adoption of some international standard unit of activity becomes necessary The International Conference of the Health Organisation of the League of Nations appointed a special committee, under the chairmanship of Dr H H DALE, to deal with this matter, and an international standard has now been instituted with the result that all preparations of insulin have the same potency.

A full account of the steps taken to this end is contained in a report[1] recently published to which Dr. DALE contributes an introduction describing the method whereby the international unit was fixed. 500,000 units of insulin were collected from the most important manufacturers of insulin throughout the world. These specimens were pooled and converted into a uniform dry, stable powder in Dr. DALE'S department at the National Institute of Medical Research at Mount Vernon. As a result of experiments in several laboratories the unit of insulin was defined by the Insulin Committee of the University of Toronto as "the activity contained in 0 125 mg. of the international standard preparation." The Conference then placed on record the following unanimous recommendations: 1 That the dry preparation of insulin hydrochloride, prepared by the Medical Research Council of Great Britain at the request of the Edinburgh Conference, should be accepted as the international standard preparation of insulin. That 1 mg of this standard contains 8 units of insulin (or 1 unit = 0 125 mg) as provisionally defined by the Insulin Committee of the University of Toronto 2 That this standard preparation be kept on behalf of the Health Organisation of the League of Nations by the Medical Research Council who will undertake to test the permanence of its potency from time to time 3 That samples of this preparation, weighing 0 100 g each, be sent to some responsible organisation in each country (such as an Insulin Committee or a Government institution), who will undertake further distribution to testing laboratories. In those countries in which no suitable organisation for this purpose exists, samples of the standard will be distributed by the Medical Research Council after consultation with the Insulin Committee of the University of Toronto, or, in case this Committee be discontinued, with one appointed by the Health Committee of the League of Nations 4 That each testing laboratory should prepare a standard of its own, and should compare the potency of this with the sample of the international standard placed in its hands for this purpose. When the latter is exhausted, further comparisons with the international standard should, where possible be undertaken by the responsible authority for the particular country. 5 That either of the following methods, of which full details are set out in separate reports, be considered as suitable for the bio assay of insulin:—

(a) *Methods Depending on the Effect of Blood-sugar: First Method*—Varying quantities of insulin that are less than the convulsive dose are injected subcutaneously into rabbits of about 2 kg. body-weight, from which food has been withheld for 18 to 24 hours and the average of the blood-sugar percentages over a period of five hours after the injection is subtracted from the blood-sugar percentage immediately preceding the injection. The number of units of insulin present in each c cm. of the preparation is then calculated by use of a formula. Each rabbit used in the assays is tested at suitable intervals with a standard preparation which is periodically compared with the international standard.

Second Method.—Alternatively, one half of a series of rabbits receives, in each case, an injection of a half unit of the standard preparation per kg, and the other half receives, on the same day, the dose supposed to be equivalent of the sample under test. The percentage fall of the blood-sugar content over a period of five hours is determined as above. A few days later the determinations are repeated on the same series of rabbits in this way that the rabbits previously receiving the standard preparation now receive that under test and vice versa.

From the relation between the falls of blood-sugar content produced on the one hand, by the standard preparation and, on the other hand, by the sample under test, the true activity of the latter in units per c.cm. can be calculated.

(b) *Method Depending on the Incidence of Symptoms in White Mice.*—The assay is carried out by comparison with a standard preparation injected simultaneously with the unknown sample on an equal number of mice from a common stock. The onset of convulsions or collapse is used as the end-point of the reaction and a mouse dose is the quantity producing convulsions (or collapse) in half the number of mice injected. During the test the mice are kept in an incubator at a uniform temperature of not less than 30° C.

---

[1] The Biological Standardisation of Insulin including Reports on the Preparation of the International Standard and the Definition of the Unit. League of Nations Health Organisation, Geneva 1926 Agents in Great Britain: Constable and Co

The Report contains articles on the standardisation of insulin in the most important centres in the world Prof J J R MACLEOD and Mr M D ORR describe the method employed by the Insulin Committee of the University of Toronto in standardising their insulin There follow accounts from other institutions—namely, E R Squibb and Sons' Research and Biological Laboratories, the Lilly Research Laboratories (Dr G H A CLOWES), the Nordisk Insulin Laboratorium and the Laboratory of Zoo-physiology of Copenhagen University (Dr A M HEMMINGSEN and Prof A KROGH), the Wellcome Physiological Research Laboratories (Dr J W TREVAN and Miss ELLEN BOOCK), and the National Institute for Medical Research, London (Mr H P MARKS) It is a satisfaction and pleasure to note that the Medical Research Council has played a paramount part in the adjustment of delicate international negotiations The practical importance of their successful outcome is far-reaching It implies, for example, that a practitioner will now be able to permit a diabetic patient to travel abroad in the confidence that he will be supplied with insulin exactly corresponding in potency to that which keeps his blood-sugar in check at home It may be hoped that this International Report will be the first of many, and that other hormones which at present are sold by commercial firms without any control at all will in the near future come under the same intelligent control as insulin

---

PUBLIC HEALTH IN CHINA.

IT is an interesting fact that in the social and political welter in which China now finds herself there should be arising in that country the strongest manifestation that has yet been made of a desire to promote public health It may be presumed that the distressing circumstances in which the Republic has been abiding for some years have accentuated for the inhabitants generally that struggle for existence which probably is harder in China than in any other country in the world, for these circumstances have not interfered in any regular way with the growth of population Human fecundity is there a marked feature, the average family of every married couple is from four to five children, and the adult unmarried are rare That much can be surmised, though there are no trustworthy statistics from which either the total population or the mortality-rates can be estimated Anyhow a vast and increasing mass of people is living in China in much the same way as their forefathers have done for over a thousand years, and families are being reared at an incredibly low cost, for, when droughts and floods are absent, sufficient food can be obtained for all, though obtained only as a return for unceasing toil With such a situation the need for public health measures is imperative, and this need is now being felt as much by the Chinese themselves as by the various populations resident in China but coming from countries where Western society has laid down scientific standards and has adopted measures of sanitary legislation

We publish in another column a communication furnished to us by Surgeon-General S H CHUAN from the Ministry of War at Peking, in which that distinguished official pleads eloquently for the allocation of the money received by the British Government in the form of the Boxer Indemnity to the promotion of public health in China We pointed out recently how right and just such an allocation would be, when publishing an earnest appeal to that effect from two representative leaders of Chinese medicine, Dr S M HOW, and Dr W L NEW, and in the same issue of THE LANCET (see THE LANCET, May 1st, 1926, p 946) Dr JOCELYN SMYLY, of the Peking Union Medical College, described the whole medical situation in China as justifying such an employment of the sums which it has been decided by our Government to hand back to China This view is endorsed by Surgeon-General CHUAN, who points to the high infantile mortality and the recurring epidemics to prove how dire the need is for an organised public health service, while the good effect of such a service can be demonstrated by the far better health conditions which prevail in the different foreign centres where small sections of the population have fallen under the influence of Western knowledge Practically wherever instructed medical diagnosis can go in China the prevalence is found of tuberculosis, dysentery, and trachoma, while venereal disease is a problem in all the urban centres Here further frequent epidemics may rage unchecked in the absence of any regulations as to notification or segregation These facts, patent to every foreigner living in China, have forced themselves on the attention of many Chinese, especially those who have received their education away from home or have benefited in China by foreign tuition And medical opinion is growing in force The medical profession in the Empire as represented by foreign trained graduates is enlarging, and a modern tendency towards intensive study of special diseases is springing up with it This means that a certain number of Chinese medical men are now focusing their attention on public health, and everywhere these men find the call for improved sanitation This fact escapes the vast Chinese populace that lives eternally overcrowded, with its homes hermetically sealed But the first remedy for such a condition of things that jumps to the Western mind would not work efficaciously in China—namely, education along general lines In Great Britain we see how, as the populace grows more enlightened, the teachings of science are more readily accepted and public coöperation is more promptly forthcoming But things would work in no such definite way in China, where for the time being kindly and authoritative administration cannot be replaced by argumentative conversations in which all-important scientific issues would get complicated by political prepossessions What is really required is the improvement of medical education in China, working hand in hand with the awakened Chinese doctors

Medical education in China has been so far conducted on philanthropic and altruistic lines, and except for the University in the colony of Hong-Kong has been almost entirely in the hands of medical missionaries, while the Peking Union Medical College, now administered by the Rockefeller Foundation, was founded by British and American missionaries The number of graduations from foreign medical schools in China amounts to about 200 annually and a similar number of medical graduates return each year from schools abroad This band of foreign-trained graduates conform to a reasonably good standard, and they would form admirable auxiliaries if the money available from the Boxer Indemnity Fund were used to promote a public health scheme Such a scheme, moreover, would have no caste disabilities to over-ride or evade, and would be dealing with a docile population which already freely accepts, for example, the practice of vaccination and the antitoxin treatment of diphtheria At the instance of the Chinese Medical Missionary Association, a Council on Health Education was formed some years ago, and the members under the leadership of Dr W W PETERS, an American citizen, have carried out health campaigns by means of the cinema, public meetings, and pictorial posters, the work has been enthusiastically welcomed in the towns where the demonstrations have been made A public health station in Peking, established through the Rockefeller Foundation by Prof J B GRANT, has already gained much practical experience upon which to found future work and the field for that work is expanding with the expansion of factory activities in the Empire, already factory laws are needed, and a public health system is obviously necessary for the construction and maintenance of legislation Lastly, there is now in China a National Medical Association which publishes a monthly journal in Chinese and English, and which has been referred to in these columns as a rallying centre for modern Chinese medicine We have received this week a Memorandum from the Association which is being presented to the British Boxer Indemnity Commission recapitulating with the force of local inspiration all the above arguments The Chinese are helping themselves, and they should be helped Therefore, again, we put forward the earnest hope that substantial sums of money, over such a period as the available total permits, should be allocated from the Boxer Indemnity Fund to the foundation of a public health scheme for the Chinese Empire

◆

COLOUR-BLINDNESS

THE facts of colour-blindness, so far as they are of importance in the affairs of life, have long been known, but their scientific explanation is a ground over which theorists continue to fight without any apparent prospect of coming to an agreement The supporters of each main theory—the Young-Helmholtz, the Hering, the Edridge Green—are accustomed first to state their theory and then to cite an array of experiments with colour-blind subjects in support of it, numerous enough to carry entire conviction to the mind of the writer, if not of the reader These theories are mutually antagonistic and the facts, being entirely dependent upon the sensations of the subjects experimented on, are such as can only be verified by psychological investigation—not such, therefore, as are susceptible to ordinary physiological or physical proof It is not to be wondered at that the average doctor, and even the average ophthalmic surgeon, is content when he has been given a practical test to distinguish the degree of colour-blindness which is dangerous for certain occupations and leaves theories to the theorists Nevertheless the scientific importance of the matter is very great, for with the process of colour vision is bound up the process of all vision, the physiological activities of the retina and of the brain Miss Mary Collins[1] approaches the subject in a new way which, while not purporting to prove anything at all, appears to us to promise in the end a real advance All the colour theories are stated while no single one and no combination of them is adopted as a thesis in support of which the writer arrays her facts These facts are limited in number, being all derived from observations taken on ten colour-blind students, all of them belonging to the common class of colour-blinds whose peculiarity is an inability to distinguish red from green Each of these students was subjected to a detailed examination with all the common tests From careful notes of their answers some interesting results emerge, some of them confirming the work of others, but some of them new The colourless or grey band in the green region of the spectrum was confirmed in all cases, and that the breadth of this band varies in different subjects, as Edridge-Green contends, was also established The existence of a second neutral band outside the spectrum in the purple is a new observation not explained by any current theory Edridge-Green's belief that there is a gradation of colour defect is entirely substantiated, but it is contended that certain results obtained are not explained by his theory Many colour-blinds use the expression "reddish-green" or "greenish-red" to describe their sensations, expressions which to the normal person are entirely meaningless Edridge-Green finds a natural explanation for this phenomenon in the case of trichromates for whom on his theory green and red are next-door neighbours in the spectrum Miss Collins found the expression used by ordinary bichromates and suggests an explanation which we confess we find ourselves unable to follow A large proportion of the book is taken up with a detailed record of the application of the various tests, and for practical purposes Miss Collins comes to the conclusion that the Edridge-Green lantern is the best of all It takes time, however, and for ordinary cases many simpler tests were found to be adequate if used with knowledge The Holmgren wool test, if used in the old way, is not to be recommended but with the pale green used as a test skein Miss Collins found that all her subjects substantially failed in their matches, and in this professes disagreement with Edridge-Green, who states that many colour-blinds can easily pass this test without detection What Edridge-Green says, however, is that *three-unit* colour-blinds would usually pass this test with success Since all Miss Collins's subjects were two-unit ones there is really no apparent ground for dispute

The fact is that the interpretation of subjective sensations is so fraught with difficulties that to prove any theory of colour-blindness is almost impossible The available material concerning the relation between retinal structure and retinal function is at the moment quite inadequate for the purpose of throwing any light upon the mechanism of colour vision in man This is, at any rate, the conclusion come to by Dr Julia Bell,[2] who after years of study of the subject has been impressed by the elusiveness of the phenomena of colour vision and by the sadly little we really know about it In this conclusion most of those who have given attention to the subject will concur The first section of her book on colour-blindness, which forms the second part of the Nettleship Memorial volume, is mainly introductory and historical The next section deals with so-called "total" colour-blindness, an affection which, inasmuch as it is usually but not necessarily combined with nystagmus, photophobia, and some degree of amblyopia, has generally been supposed to have little connexion with ordinary dichromatism or "Daltonism" in which none of these defects are typical There seems to be no doubt that in the typical totally colour-blind person the spectrum is identical with that seen by the normal eye under dark adaptation In this respect total colour-blindness differs from another condition characterised by nystagmus, photophobia, and amblyopia—viz, albinism—although in one case of this latter condition (recorded by Rugg-Gunn) there was a definite shortening of the red end of the spectrum Moreover, in both conditions there is definite pathological evidence that the structure of the foveal region of the retina is not normal As to the hereditary factor in the causation of total colour-blindness, although it is undoubtedly a familial disease, the pedigrees collected do not show one case of its occurrence in more than a single generation and only one of its occurrence in more than a single sibship (children of a common parentage). Consanguinity of parents appears to play an important part, as in over one-quarter of the cases it was present, a feature which puts it into relation with retinitis pigmentosa and congenital stationary night blindness , in both of these diseases, however, the inheritance is commonly through several generations.

---

[1] Colour-Blindness with a Comparison of Different Methods of Testing Colour-Blindness By Mary Collins, M.A. Ed, Ph.D, Lecturer on Applied Psychology, Edinburgh University, with an introduction by Dr James Drever London Kegan Paul, Trench, Trübner and Co 1925 Pp 237 12*s* 6*d*

[2] Colour-Blindness By Julia Bell, M.A, M R.C S, L R C P Being Part II of the Nettleship Memorial Volume on Anomalies and Diseases of the Eye (the second volume of the Treasury of Human Inheritance, edited by Karl Pearson F R.S, for the Francis Galton Laboratory for National Eugenics) Cambridge University Press 1926 With 15 plates of pedigrees Pp 267 45*s*

Coming to congenital colour-blindness of the more ordinary type, or "dichromatism," whose most common symptom is a confusion between red and green, the question is discussed whether in these cases, in which apparently only two of the spectral colours can be distinguished by their tints, the two colours seen by the dichromate really correspond to the yellow and blue as seen by the normal person, or whether, as Edridge-Green maintains, they really correspond to the colours most widely separated in the spectrum—namely, red and violet Dr Bell inclines to the former view on the ground that the colour-blind themselves generally recognise yellow and blue without hesitation, whereas with red and green they nearly always hesitate Moreover, in acquired conditions such as toxic amblyopia perception of red and green is always the first to go and the last to return. A confirmation of this view is found in a rare case of unilateral colour-blindness described by von Hippel in which the patient could interpret the sensations experienced with the affected eye by reference to those of the other eye which was normal For his affected eye two colours only occupied the spectrum—namely, yellow and blue Other unilateral cases have been described by various observers but they are very rare. Undoubtedly the most valuable part of Dr Bell's book is not her criticism of the theory of colour-blindness, but her collection of pedigrees illustrating the hereditary nature of the condition It has been repeatedly stated on theoretical grounds that for colour-blindness to become manifest in women the father must be colour-blind and the mother must also be a carrier (i e , she must have had a colour-blind parent), and further, that all the sons of a colour-blind woman must be colour-blind This does not turn out to be true without exception, but it does hold good in a great majority of the 91 cases collected Colour-blindness belongs to that group of inheritable diseases which is mainly manifested in males and transmitted by their unaffected daughters, but not by themselves directly to their sons Of the 235 pedigrees given 35 were collected by Nettleship The volume marks a progress in the young science of heredity to which Nettleship, during the latter part of his life, made such important contributions

◆

ÉMILE COUÉ.

Émile Coué, whose death was announced at the beginning of the week, was a singular and sympathetic figure He had practically no scientific equipment, and does not seem to have been at all well read in either philosophy or psychology, but there can be no doubt that from ministrations along his simple formula many people widely differing in physical and mental qualities received benefit, though we have seen no facts or even surmises as to the permanency of the improvements During his visits to this country he found admirers as well as scoffers, but there was no hostility to the man, for Mr Coué's charming and parental manner, which aroused in his subjects a feeling of delightful dependence, also disarmed anything like venomous criticism A few reflections which were offered by English psychologists with a view to check a public enthusiasm that might have been mischievous constitute all the effort that was made on this side of the Channel to set up any scientific estimation of his theories, and the general conclusion was arrived at that any process inducing a belief in cure, under whatever disguise it might appear, would help considerable groups of nervous sufferers, and might influence the progress of bodily disease

Annotations.

"Ne quid nimis"

THE BIRTHDAY HONOURS

As had already been foreshadowed publicly, the postponed list of Birthday Honours does not include the name of many scientific or medical men Two medical men have received knighthoods, Sir Alexander MacCormick, the well-known consulting surgeon at Sydney, receives a K C M G , and Mr Alfred H Evans a civil knighthood, and Mrs Scharlieb, consulting gynæcologist to the Royal Free Hospital, receives the D B E Major-General R S Hannay, Deputy Director Medical Services, Southern Command, and Surgeon Captain R St G S Bond, R N , receive the C B Dr J O Shircoe, Director of Sanitary Services in Tanganyika, is appointed C M G Mr Ernest Clarke is appointed C V O , and Colonel G W Heron, Director of Department of Health, Palestine, receives the C B E In the Military Division of the Order of the British Empire Miss M D Knapp, chief lady superintendent, Queen Alexandra's Military Nursing Service in India, is appointed C B E , and Lieut -Colonel H R Brown, I M S , Captain William Bligh, M D , R A M C, Major J W Malcolm, R A M C , and Dr D M. Macphail, Dr W M McDonald, Dr F E Whitehead, of the Colonial Medical Service, are appointed O B E The same honour is awarded to Major William Egan, R A M C , Assistant Director of Medical Services in Scotland , Major C H H Harold, M D , Assistant Instructor in Hygiene, Aldershot , and Lieut -Colonel C E Steel and Major W. C Lowe, of the Royal Army Veterinary Corps Mr W G Hunter, Deputy Accountant-General of the Ministry of Health, is appointed C B E , and among the Indian awards Prof A. K Dalal, of the Grant Medical College, Bombay, is given the O B E , the M B E being awarded to Mr A G Butt, of the Office of the Director of Medical Services , Major J. H A Donnelland, resident medical officer at the Jamsetjee Jeejeebhoy Hospital; and Major H C Craggs, I M S Lieut - Colonel T W Harley, I M S , district medical and sanitary officer and superintendent, Medical School, Madura, Madras, receive the C I E Major H W V Cox, civil surgeon, Punjab, receives the I S O , while the Kaisar-i-Hind medal is awarded to Miss F A Hodgson, superintendent of Lady Minto's Indian Nursing Association , Miss Agnes Scott, M B , the secretary of the Countess of Dufferin's Fund , Dr J D O'Donnell, chief medical officer of the Kolar Gold Fields , and Major J A H Holmes, surgeon to the British Station Hospital, Quetta

The majority of those receiving titular honours are rewarded for political and public services, but two of the new knights represent the influence in the development of the health of the nation which is exercised by sport and games, an influence that is so freely endorsed by the Royal Family Sir George Rowland Hill, Chairman of the Greenwich Conservative Association, is largely responsible for the fine and orderly expansion of Rugby Union football as a national sport, while Sir Francis Lacey has been for a long generation the untiring secretary of the M C C In this capacity he has been the executive officer in a complete transformation of the headquarters of cricket, as well as the politic adviser to succeeding presidents and committees, in whose hands there have lain over and over again responsibilities of national and even international significance

UNILATERAL PHRENIC PARALYSIS.

We publish elsewhere in this issue an admirable example of the way in which the deductions of accurate clinical observation may be confirmed and amplified by laboratory experimentation Last year we published a paper by Sir Charlton Briscoe pointing out that paralysis of one half of the diaphragm was commoner than the uncertain radiological signs which it exhibits had led us to suppose and that the main cause of this paralysis was simple mechanical pressure on one phrenic nerve Lady Briscoe now gives a summary account of her experimental examination of the effects of pressure on the phrenic, fuller details will be found in the current *Journal of Physiology* (vol lxi, p 353) She shows in the first place that the normal discharges of the respiratory centre can be prevented from reaching the diaphragm by a degree of pressure which we may believe can be achieved in the living body, without much difficulty, through a growing tumour or an enlarging gland, for it is less than diastolic arterial pressure The blocking effect depends on at least four variables · the degree of pressure, its duration the size of the compressed nerve, and the length of it which is compressed A weight, for example of 400 g achieves in ten minutes the same result as 80 g in 90 minutes; large nerves, such as the brachial plexus, are more resistant than small nerves, such as the recurrent laryngeal Just how the effect is produced needs more explanation: Lady Briscoe failed to find any very definite histological changes The importance of the time factor suggests that conduction fails when something viscous has been squeezed out of place; the deformation, whatever it is, is easily corrected, for the nerve begins to conduct again almost at once when the pressure is taken off. The diaphragm is commonly in postural tone and pressure blocks the motor impulses before it blocks those which maintain tone, and when the pressure is released after producing complete block, motor impulses get through first If the nerve is paralysed quickly with a big pressure, loss of tone is complete and the dome of the corresponding half of the diaphragm rises high in the chest It is interesting to note that the displacement is not nearly so great when a small pressure produces the same degree of block in a longer time, suggesting that the diaphragm has within itself a certain capacity of compensation for the loss of central impulses Lady Briscoe also records the rather unexpected result that the stronger discharges from the respiratory centre produced by CO_2 dyspnœa or stimulation of an afferent nerve will not force a block through which the weaker impulses of quiet respiration can not pass, the implication is that the diaphragm is not concerned in excessive respiration

Recognition of the fact that pressure reduces conductivity slowly and does not necessarily abolish it suddenly, explains many of the obscurities which are seen on X ray examination In complete paralysis of one phrenic, there is inverse movement—i e, the sound half of the diaphragm descends and the paralysed half is pulled up mechanically Partial blocking of the nerve produces partial paralysis of the muscle; moreover it delays the onset of each contraction and has less effect on tone than on motility. Hence, varying degrees of pressure can produce almost any radiographic picture, and, since partial is commoner than complete block, many cases yield dubious results which are open to more than one interpretation. Lady Briscoe's inquiry has, however, gone a long way towards clearing up the difficulties

KLEPTOMANIA AND DISHONESTY.

THE summer sales if we may believe the statement of a correspondent responsible for the conduct of a large millinery establishment offer a happy hunting-ground for the kleptomaniac But, apart from the special opportunities offered at these orgies of bargaining now in full celebration, there are perpetual instances occurring in the police-courts of thefts from counters when the defence of mental instability taking the form of an irresistible impulse, is put up Having regard to the wide authority there is for the belief that in some instances these thefts are the vagaries of irresponsible people, the fact remains that the majority of the cases are an exhibition of flat dishonesty Dr Antheaume in *Le Matin* writing on an epidemic of thefts perpetrated by women from the counters of large shops, went as far as it is possible to go to explode the theory of irresponsibility by one of his arguments which it is difficult to get over "Can we grant," he asked "an overpowering impulse in an otherwise honest person as the reason for thefts from the display counters, when there are no instances extant of the goods being returned on the impulse disappearing?" The question is pertinent, for in a good many cases which have formed the subject of legal inquiry the accused person has been found in possession of a store-house of stolen goods On the other hand, this very occurrence has been used as a proof of the mental instability of the accused it being argued that no one really sane would acquire things without putting them to any use—if unsound to this degree why not unsound to the point of pathological kleptomania? The whole story, however, is not so simple That a pathological impulse to steal really exists is well known Maurice Healy describes a case in *Mental Conflict and Misconduct* with an interesting account of his findings as to the unconscious motivation of the impulse, and patients occasionally come for treatment of the condition before they have fallen into the hands of the police In forming a judgment concerning a particular case the skilled investigator would be guided to a great extent by the existence of other symptoms, for the impulse is, as a rule only one detail in a larger picture The patient's description of the impulse is important, for it would be expected to produce the same state of mental tension, when resisted, that is known to occur when other pathological compulsions or inhibitions are in question; and this state is not likely to be described by the merely dishonest delinquent who pleads irresponsibility In the absence of skilled investigation however the plea of "kleptomania" can carry little weight and there is no doubt that it is often advanced when the pathological basis for it is slight or non-existent.

A DEVICE FOR PURIFYING VACCINIA VIRUS.

THE difficulties met with in attempts to procure filtrates of the vaccinia virus through filters of the Berkefeld or Pasteur-Chamberland type have been recorded by numerous workers whose experiences are summarised in the report to the Medical Research Council published last autumn by Dr. M H Gordon[1] The virus appears to be adsorbed by the filter-candle The fact that this virus is not a filter-passer has been confirmed by recent observations made by Dr Myers Coplans who, in the *Journal of Tropical Medicine and Hygiene* of April 15th and May 1st describes an alternative device for separating it in quantity from epithelial and other tissues This device is new and ingenious, taking the form of slow wick-syphonage; it is an outcome of the author's experience in connexion with the purification of water in the field It is based on the well-known physical phenomena of capillary attraction Dr. Coplans points out that if one end of a cotton or asbestos wick is dipped into water, the water rises throughout its substance, though, owing to imprisoned air, the rate of rise may be very slow. When the water has risen to a sufficient height in the wick to permit the adjustment of an overhang, dripping takes place from the free end Columns of liquid have united within the fibres and the action of flow and discharge from the free end of the wick is essentially the result of internal wick-syphonage If, as a preliminary, the wick be plunged into boiling water, the contained air—a potential air-lock—is expelled and the wick immediately becomes thoroughly moistened The wick may then be gently pressed to expel the excess of water. If the moistened wick be now arranged so that one end is immersed in liquid contained in a vessel and the free end overhangs the outside of the vessel to a level below the level of the liquid contained within the vessel, wick-syphonage is immediately set up, and clear liquid discharges from the free end of the wick, the drip being maintained so long as the free end overhangs below the level of the liquid contained in the vessel For details of the special application of wick-syphonage to the purification of vaccine virus Dr Coplans's paper must be consulted For this purpose he uses cotton wicks free from asbestos (which apparently arrests the virus in the process of syphonage) 1 in in diameter and 7 to 8 in. in length In the process of freeing the vaccine virus from epithelial and other tissue by wick-syphonage, a slime deposit always forms rapidly upon the surfaces of the submerged portion of the wick Indeed, a potent syphonate is more rapidly obtained when a very large surface of wick plentifully slime-coated is submerged The slime deposit, which consists of epithelial and other tissue containing the virus, is not intended to function as a bacteria-arrester. The lymph used in these experiments had been previously rendered free from pathogenic organisms The first syphonate, consisting of the wick "retention fluid," must always be discarded In the experiments for the freeing of the vaccine virus from calf lymph containing 50 per cent glycerine, it was found that the establishment of maximal potency of the wick syphonate did not occur until after the wick had been functioning for one week at least The potency of the liberated virus was subjected to stringent biological tests, rabbits inoculated intravenously therewith developing generalised vaccinia

---

[1] THE LANCET, 1925, ii., 826

We call attention to this device because the virus of vaccinia is being closely investigated just now by many groups of workers Its specific lesions are so readily produced on the skin of a rabbit that it is comparatively easy to work with, and for this reason may prove a useful guide to the elucidation of other viruses far more difficult to study experimentally while of greater pathogenic importance

THE LEAGUE OF NATIONS AND THE TRAFFIC IN OPIUM AND DANGEROUS DRUGS

THE Advisory Committee of the League of Nations on the Traffic in Opium and Dangerous Drugs recently held its eighth session in Geneva under the chairmanship of M. Bourgois, the French representative Germany, China, Great Britain, India, Japan, Netherlands, Portugal, Serbia, Siam, and Switzerland were also represented Mr Pinkney Tuck, instructed by the United States, attended in an unofficial capacity, and Colonel Arthur Woods, a former police commissioner of New York, took part in the proceedings for the first time as an assessor It appears that the Geneva Convention of February, 1925, which it was claimed would "accelerate from day to day and from month to month" the control of the dangerous drug traffic, still lacks ratification by the ten Powers (including seven of the States Members of the Central Board, two of which must be members of the League Council) without which that convention cannot come into force Meanwhile the Committee received sinister reports of the confiscation of very large quantities of opium and drugs in the course of the extremely serious illicit traffic which is going on The Committee again announce, what indeed was common knowledge when the first Hague Opium Conference assembled fifteen years ago, "that the quantity of drugs manufactured is considerably in excess of medical and scientific requirements" The Committee accordingly thought it wise to confine itself to examining the situation in the light of The Hague Convention of 1912, which is the only international instrument for control of the traffic in drugs of addiction now in operation Turkey has at length ratified that Convention, reports were considered from several signatory countries from which it appeared that exports of opium from the Persian gulf were still seriously excessive, that consignments of scheduled drugs under forged labels is not uncommon, and that smuggling by post to the Far East calls for repression

As pointed out in THE LANCET of Nov 20th, 1925, the Geneva Conferences failed to adopt the principle, advocated by the American delegation, of limitation of production of opium or to medical purposes, and at the same time postponed the operation of the requirement of The Hague Convention to suppress the traffic in smoking (or "prepared") opium Except for the change of policy of the Indian Government now endorsed both by the Council of State and the Legislative Assembly, there is little progress to be recorded and there is perhaps some apprehension lest the gloomy anticipation of the competent critic of the Geneva Conferences, Mr Gavit, may prove correct—viz, that the Convention of last year may be "a thing of printed paper with the odds heavily against its ever being anything else"

PARATHYROID EXTRACT IN INFANTILE TETANY

IN a recent issue of the *Journal of the American Medical Association* (vol. lxxxvi, No 22) will be found an account by Lynne Hoag and Helen Rivkin of the effect of treating infantile tetany with parathyroid extract (Lilly), which is made up by the method recently introduced by Collip They found that the treatment is very effective, and that there is a rapid improvement in the symptoms, and that the blood calcium returns to normal within 24 to 48 hours Their experiments show that an injection of about 5 units of this parathyroid extract per kg of body-weight gives a rise of about 1 mg of the serum calcium per 100 c cm Five units should be given for a period of about 24 to 36 hours They, in common with other observers, emphasise the necessity for great caution in the administration of the extract, and point out the necessity for repeated blood calcium estimations In the same journal, on p 1683, there is an account of the treatment of pulmonary tuberculosis by injections of this hormone The writers, Burgess Gordon, Jesse L Roark, and A Kenneth Lewis, maintained a serum calcium content of a series of 60 tuberculous patients at a high level for a considerable period Their general conclusion was that although some of the symptoms may be benefited, the general course of the disease remains unaffected The only value in the treatment consisted in its effect upon pulmonary hæmorrhage This was always relieved, and they conclude that the hormone will be of the greatest value in treating this complication of tuberculosis.

PSYCHOLOGICAL TESTS FOR IMMIGRANTS

THE late war brought in its train not only a number of social problems, but an increasing possibility of the application of psychology towards their solution The problem of immigration has been one of the most difficult that the United States have had to face In early days legislation was designed to control the numbers of incoming persons on the grounds of gross physical ill-health, obvious insanity, and criminality The war, however, aroused in America as elsewhere a considerable amount of national pride and racial passion, and psychology has been used to justify the selection of immigrants who are regarded as mentally as well as physically fit to enjoy the privileges of American citizenship Behind this will to select the best that Europe had to offer lurked a certain prejudice in favour of those persons who came from the Northern European countries to the exclusion of those from the Slavonic and Latin countries This hypersensitiveness to racial differences is a phenomenon not strange to America, where the colour problem has influenced policy for more than half a century Dr B Boody has recently published[1] a fair-minded and exhaustive review of the entire field of immigration legislation and the medical and psychological investigations that have contributed to the changes in the laws The procedure at Ellis Island is described, and the writer shows herself not only in sympathy with the immigration officials, but with the half-bewildered persons of all ages and nationalities who pass through the barriers into America. The mental tests adopted for the elimination of mental deficiency are given in statistical tables. Binet tests were used together with modifications of the American Army Beta tests. It was found as a result of experiments that the elimination as far as possible of language from the investigations is of advantage since it is not always easy to convey the idea of tests in different languages; moreover, one language may demand circumlocution or a complex phrase for what is a simple expression in another. The tests used seemed to dispose of the view that there was much, if any, racial difference in intellectual ability or in perceptual acuity. Selection on the whole has to be made on the basis of the individual, and any preconceived notion as to the inferiority of this or that race or nationality has to be reviewed in the light of facts brought out by testing each case under the best possible conditions.

ARSENIC IN APPLES

MUCH has been heard recently of the presence in or on apples of appreciable quantities of arsenic which has remained there to the prejudice of buyer and seller alike after the use of insecticidal spray. A recent paper[1] by Dr. F. T. Shutt, Dominion Chemist, is of value in clearing up the issue. In this paper, entitled the Examination of Canadian Sprayed Apples for Arsenic, Dr. Shutt describes the results of his examination of 43 samples of apples grown in Nova Scotia, Quebec, Ontario, and British Columbia. In half of the samples he was unable to detect any arsenic at all; about one-sixth contained traces of arsenic in a proportion of less than 1/10,000th of a grain per pound; and in the remaining third arsenic was present to the extent of 1/10,000th to 1/190th of a grain per pound. For the purpose of this analysis he examined only the skin, calyx, and stalk, for he states "it is generally agreed that the flesh of the apple is practically free from arsenic, even though 'ponderable amounts' of this poison may be present on the skin." Dr. Shutt points out that, even where the maximum amount of arsenic was found, it would be necessary to eat three pounds of raw apples at a time in order to ingest the minimum medicinal dose of arsenic.

A POST-GRADUATE HOSTEL FOR LONDON

AT the invitation of Sir D'Arcy Power a meeting was held at the Imperial Hotel, Russell-square, on Tuesday afternoon, July 6th, to consider the formation of a Post-Graduate Hostel, to be a centre of welcome for medical visitors to London. It is doubly a point of honour with the medical profession in London that such a material assistance for entertaining the stranger within our gates should be instituted, for not only do they desire to be the hosts of colleagues from abroad, but in many instances they have been the recipients of kindnesses abroad—return for which there is no opportunity of affording. Visitors from our colonies and from other lands do not obtain in London fitting opportunities for interchange of views with our professional men; seldom do they have time to visit, professional and private courtesies, though freely offered as we know, cannot be organised. If a hostel is instituted it will be possible to arrange that provincial as well as London exponents of our science and art should meet overseas visitors in a regular manner and to mutual advantage. It is proposed that at the hostel there should be opportunities for interchange of opinions without the medium of lectures, although different speakers will be put forward to deal with various aspects of disease in order to initiate discussions. In the first instance the premises of the hostel will be two large rooms placed at the disposal of the organisation by the Imperial Hotel, so that visitors can have a centre of social exchange. For the present it is proposed to hold discussions in the shape of symposia three or four times a week. Visitors will pay the ordinary hotel prices, but will be free of the two rooms at any time.

The provisional committee of the movement consists of Sir D'Arcy Power, as president; among the vice-presidents being Dr. Alfred Cox, representing the B.M.A.; Sir StClair Thomson and Mr. H. J. Patterson representing the Royal Society of Medicine; Sir G. Lethal Cheatle and Sir Thomas Horder. Dr. A. P. Birtwistle will act as director. Approval of the scheme has been expressed by many professional leaders in different parts of the country, and it is intended that a vice-president shall be obtained representing every English-speaking medical school and the more important foreign schools.

SIR WILLIAM MACEWEN

AT the recent commemoration of its founders and benefactors the University of Glasgow honoured especially the memory of Sir William Macewen, and to Prof. Archibald Young fell the task of delivering an oration on the life and work of his predecessor in the Regius Chair of Surgery. This oration has now been published[1], and repays study, because in telling of Macewen's achievements Prof. Young has given an idea of his personality; in describing the work which had far-reaching results he has not forgotten to indicate the sacrifices which made that work possible. The whole of this great man's life, says Prof. Young, was work—purposeful work. He could not be imagined doing anything merely to pass the time away, and he had determined to devote all his powers, unceasingly and without rest, to making advance in orderly fashion along the line of progress. Macewen, as is clear from Prof. Young's admirable portrait, had the capacity for taking pains which may or may not be called genius, and he let slip no chance of gaining knowledge in whatever occupation he was engaged. Since his observations were accurate and his conclusions never drawn without meticulous examination of all the evidence, he was naturally confident in his opinions and unwilling to modify them. For the same reason they seldom needed modification, and most of his theories and careful methods are embodied in the practice of surgery to-day. Although Macewen had the attitude of philosophic doubt proper to a scientist, in such a man this attitude could never be confused with the philosophic vagueness which often passes for it. His mind was well equipped, and to this mental efficiency he added the energy and the virility of a leader able to get the last ounce of work out of his assistants, because he gave the last ounce himself. Such a man—such a type—is a natural response to the demands which research and practice began to make last century, and of Macewen's services to humanity there can be no doubt. Every student ought to be familiar with his name, because it is attached to instruments and technique which are in daily use; whilst every surgeon, as he mechanically goes through the ritual of aseptic operations, is making use of methods Macewen did much to introduce. He elaborated and made intelligent the surgery of bones, and he laid many of the foundations of cerebral surgery. In these things he deserved well of those who follow him and his reputation is assured. "He was a great man" says Prof. Young—"one of the world's great men." But Job has said that great men are not always wise, and Macewen suffered in a way which Prof. Young points out. "He earned respect, he excited admiration in virtue of his energy, his industry, his originality of thought, his brilliant research. He kindled in his students and in his assistants something of the spirit of investigation with which he was himself so richly endowed. It is extremely doubtful, however if he ever could be said to have gained—or even if he desired to gain—the affection of those who were his most loyal helpers . which was to be regretted all the more that such affection could easily have been his " This was the defect of his qualities, and was possibly an inevitable corollary of the singleness of purpose which made his life so productive Such a man's victories, and their cost, cannot fail to be interesting, and Prof Young has done a service by presenting so lucidly his own impressions of them

---

THE HEALTH OF THE ARMY IN 1924

During and immediately after the war the annual reports on the health of the Army fell into arrears, but the report for 1924, now issued, brings the series nearly up to date Unfortunately, it is the last to be signed by Sir William Leishman, under whose régime as Director-General these reports have been made more useful than they were before The total number of persons concerned remains almost the same as in 1923 Amongst officers there was an increase in the death-rate from 3 93 per 1000 to 5 86, but the health of the 192,283 other ranks improved Their total admissions amounted to 484 7 per 1000 during the year, malaria being the most frequent single cause, and their general death-rate was 2 80 as compared with 2 84 in 1923 Influenza caused more deaths than previously, but the figures for general injuries, dysentery, malaria, tubercle of lung, and digestive disorders all showed a diminution Fewer men had to be invalided—principally because there were fewer cases of middle-ear disease owing to greater care in recruiting and the provision of otoscopes in recruit inspection-rooms, and invaliding for tubercle of all kinds was reduced from 1 34 per 1000 to 1 03 As regards particular diseases it may be noted that there were 210 cases of enteric, 16 of encephalitis lethargica, and only 14 of alcoholism Kala-azar was successfully treated with " Von Heyden 471," even in cases which had become refractory to tartar emetic The incidence of malaria increased from 68 7 to 71 0, but the death-rate was reduced from 0 14 to 0 08 ; each case, moreover, lasted a shorter time and there were fewer constantly sick In 84 per cent of cases the parasite was recognised microscopically, as compared with 63 per cent in 1923 Amongst officers as amongst men, malaria is the commonest cause of admission to hospital, but there were only 290 cases as against 365 in the previous year In the treatment of pneumonia anti-pneumococcal serum gave less hopeful results than previously Tubercle accounted for 1 5 admissions per 1000 compared with 1 8 in 1923 There were 39 fewer cases altogether and 57 fewer invalids ; the admission rate on the Rhine dropped by 50 per cent The incidence of venereal disease was slightly reduced, from 56 4 per 1000 to 47 8, and on the Rhine it fell remarkably from 136·3 per 1000 to 38 4 , this reduction was most noticeable in syphilis, against which self-disinfection seems to be relatively more successful Twenty per cent of infections in the Army at home are contracted on leave, when prophylaxis is apt to be neglected , at Quetta only two men contracted syphilis in a series of 4788 cases in which preventive treatment was given Special research on the electrical treatment of gonorrhœa is still going on, but is incomplete An interesting outbreak of typhus fever (with a Weil-Felix reaction) occurred in six men with no lice who were living an open-air life and were well fed They were non-infectious, but had been associated with herdsmen on grazing land, and possibly they were infected by ticks It is found that in modern barracks there are fewer cases of tonsillitis than where the accommodation is less satisfactory There have been fewer cases of scabies and the average length of treatment has been reduced to six and a half days Post-anæsthetic vomiting has greatly diminished since vinegar inhalations have been given at the end of anæsthesia. Operating rooms and out-patient rooms are being improved and given better equipment as funds become available Rejection of recruits at entry and six months after entry have been reduced by special education of the recruiting officers The chief cause of rejection was loss or decay of teeth The number of teeth treated per person has increased from 3 48 to 4 18, and in India the proportion conserved has approximated to the home standard of 70 per cent Correlated with this dental care there are fewer admissions for diseases of the teeth and gums, for tonsillitis and for " other digestive disorders " A new feature of the report is the daily sick-rate for Woolwich cadets This is given as 27·17, which compares unfavourably with Sandhurst (13 22) , but the difference, at any rate partly, is accounted for by the frequency of local injuries at Woolwich

SANOCRYSIN TREATMENT IN SPAIN

In an article recently reprinted from the *Revista Medica de Barcelona*,[1] Dr Luis Saye, supernumerary professor to the Barcelona Faculty of Medicine, gives the results of treating 32 cases diagnosed as pulmonary tuberculosis with Mollgaard's sanocrysin, supplemented in some cases by his serum All the patients were treated in hospital and many different clinical types were included Dr Saye's method was to give an initial dose of 0 1 to 0 15 g (according to weight) intravenously, and before giving a second dose he waited until the effects of the first had passed off Gradually the amount given was increased up to 1 0 g or even 1 5 g , but the intervals between doses were also lengthened, from about five days to 10 or 12 In severe febrile cases the quantity was increased more slowly The serum was used when there was shock or severe albuminuria, or where large doses of sanocrysin were given to feeble people, but the author expresses no clear opinion on its value The symptoms noted were as follows Nausea and vomiting occurred at the time of injection in some cases , later on there was a febrile reaction of varying intensity and duration, and all the patients developed albuminuria at some stage, although it was rarely severe Other untoward symptoms were digestive disturbance, stomatitis, and exanthemata In only one case was severe shock observed, and this passed off in a few hours Although bronchitis sometimes appeared no appreciable metastatic focus was observed during the course of treatment, and in many patients the lesions were appreciably reduced Dr Saye classifies his results as (1) negative—by which he apparently means unfavourable, 3 cases , (2) nil, 6 , (3) improved, 6 , and (4) greatly improved, 17 His report includes full synopses of all the cases, and, in some of them, X ray photographs showing the condition of the lungs at various stages There are also numerous charts giving temperature, weight, and blood counts Emphasis is laid on the necessity for regulating the treatment according to careful observations of each individual patient , no fixed rules, says Dr Saye, can be laid down for the amount of the doses or the lengths of interval between them He considers that sanocrysin has a specific effect on the tuberculous process and that there are wide indications for its employment, but that does not, of course, justify neglect of other therapeutic measures such as rest, diet, fresh air, and, when indicated, artificial pneumothorax Much labour was evidently spent in drawing up this report which must be considered a solid contribution to the literature of sanocrysin All the facts and figures seem to have been carefully sifted

Belgian Medical Tours —The *Bruxelles Médical* has arranged a series of tours in August and September to the Canary Islands, the ports of France, and to the Eastern Mediterranean Particulars may be had from the Bruxelles Médical at the Office Belge des Compagnies Françaises de Navigation, 29, Boulevard Adophe Max, Brussels

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

---

CLXXX.—THE TREATMENT OF CATARACT.

CATARACT may be classified as (*a*) progressive, (*b*) stationary. The progressive group includes the following subgroups: (1) Senile. (2) Complicated: (*a*) general disease—e.g. diabetes; (*b*) ocular disease—e.g., irido-cyclitis, retinitis pigmentosa, retinal detachment, choroiditis. (3) Occupational, from excessive heat as in glass-blowers. (4) Trauma from perforating injury or contusion. The stationary group may be: (1) lamellar; (2) congenital (total, axial, dotted, coralliform); (3) capsular (anterior from corneal ulcer in ophthalmia neonatorum, posterior from developmental defect).

Only the more important among these classes are here considered.

Senile Cataract

The ophthalmoscopic appearances of incipient senile cataract are as follows:—

(*a*) Radial striæ: dark sectors with the apices towards the centre of the pupil. (*b*) Coarse masses of opacity in the peripheral cortex, often behind the lower part of the iris. (*c*) Opaque meshwork in the pupillary area, increasing to a perinuclear opacity. (*d*) Saucer-shaped opacity in the posterior cortex, spreading towards the periphery.

A progressive cataract may be labelled *senile* if (1) the anterior parts of the eye appear normal; (2) the pupil reacts well to light; (3) good perception and projection of light are present, and any visible fundus is normal; (4) it is bilateral or incipient in the second eye; (5) other causes are absent.

Course of Incipient Senile Cataract.—The type with fine radial striæ progresses very slowly. In other types it is unwise to prophesy: the condition may remain stationary for some years and the vision may even clear slightly without any treatment; but it may also fail rapidly in a few months.

Mature Cataract.—In mature cataract (1) vision is reduced to hand movements; (2) the red reflex with the ophthalmoscope from the fundus is absent or nearly so; (3) the whole of the anterior surface of the lens is grey when viewed by oblique illumination.

Medical Treatment.

Where the opacity is central, mydriasis may assist the vision, and homatropine, 1 per cent., or atropine, ¼ per cent., may be used, but a watch must be kept that the intra-ocular tension does not rise. The former drug should be used at first as it can be counteracted by eserine should the tension increase.

From time to time various forms of treatment are vaunted as staying the course of senile cataract and as clearing it. It is doubtful whether any of them has the slightest effect; accounts of beneficial result are to be looked upon with suspicion. The biochemistry of the lens is still in an embryonic stage, and the ætiology of senile cataract is still sub judice. This subject is one of the many in which it is difficult to maintain a true balance between the claims of new remedies, which may be of real therapeutic value or may be tinged with chicanery. To have any chance of success they must be tried in the early stages of the disease, at a time when the patient may be unaware of any visual defect, apart from the need for glasses. Now, it is inadvisable to inform the patient of his condition at such a stage, because (1) treatment is nearly certain to be useless, (2) the condition may remain unchanged for many years, (3) the fear of impending blindness may cause needless prolonged depression. In cases where the diagnosis has to be declared, there can be no harm in trying some form of treatment, though a warning note should be sounded as to its probable inefficacy, and the prolonged period over which it must continue.

Among the treatments given are the following: (1) Solutions of potassium iodide in increasing strengths used in an eyebath for five or ten minutes several times a day. (2) Dor's ointment, "calcic-alkaline-iodide" well massaged into the conjunctiva twice daily. (3) Extract of parathyroid gland by the mouth in doses of 1/10 gr. twice daily.

Surgical Treatment

Mature Senile Cataract.—Some surgeons do not advise the extraction of a mature cataract if there is good vision still in the other eye. I consider this to be wrong for the following reasons: (*a*) The stage of maturity is the best for operation; if left to become hypermature, the capsule may become thickened and give rise to difficulties. (*b*) The patient's recuperative powers get less as age advances, though octogenarians often do well. (*c*) The unilateral loss of visual field is restored. (*d*) A successful result ensures the patient against a blind old age.

Immature Senile Cataract should be removed from one eye where the visual disability of both is such as markedly to handicap the patient in his vocation. In most cases of extraction of immature cataract the lens comes away leaving but little residual cortex, and a rapid convalescence and restoration of vision result. There is, however, a danger of clear cortex adhering to the capsule and this will become opaque and take some time to be absorbed. It may even set up iritis and secondary glaucoma, though this is not often of a serious variety.

Bilateral Extraction.—Should operation on the second eye be performed, if that on the first has been successful? A man can see better with two eyes than with one, and in comparatively young persons (under 60 and healthy) I advise extraction of the second cataract when it is approaching maturity. But for patients whose prospect of life is not long the risk and discomfort of the second extraction is hardly worth while. My practice is to discuss it with the patient, and to operate only if he is insistent.

Results of Operation.—In experienced hands the visual results of uncomplicated cases are very satisfactory. Some 85 or 90 per cent. can read ordinary print with strong convex glasses (about 14 D), and require about 11 D for distance.

Diabetic Cataract

In most cases this variety is senile cataract occurring in a diabetic. Diet and insulin treatment would appear to have no effect on the course of the cataract. The prognosis of the result of operation is almost as good as in the simple senile variety. Iritis and hæmorrhage are occasional sequelæ, but seldom prevent a final good result. Patients have died in coma after cataract extraction and therefore if acetone or diacetic acid is present in the urine, proper dietetic treatment should be instituted and the patient be stabilised in his new regime before operation. To old patients who are much wasted by diabetes and who refuse to diet, a dose or two of insulin may be administered as a preparation to operation.

Other Types of Cataract

Glass-blowers Cataract.—These cases are said to do well with extraction.

Traumatic Cataract.—Occasionally a contusion opacity (of the posterior rosette type) will clear in a month or two, and an opacity along the track of a foreign body may also resolve. As a rule, traumatic cataract will require removal, but it is often associated with damage to the iris and ciliary body, and excision of the globe may be necessary for the avoidance of sympathetic ophthalmia. These cases may give rise to much anxiety.

Lamellar Cataract.—The lens should be removed if the opacity is so large and dense that a vision of 6/18 cannot be expected. If the opacity is small and central, an optical iridectomy may be considered.

Bilateral Complete Congenital Cataract.—Operation should be early, to assist the development of the retinal macula. Some mental deficiency is often present.

Methods of Lens Removal.

Discission—In children and young adults up to the age of 20 or 25 the lens is soft and is removed by tearing the anterior capsule with a discission needle, thus the aqueous obtains access to the lens fibres, and gradual solution occurs Sometimes the fibres swell up excessively and necessitate a corneal incision for their removal (curette evacuation)

Extraction—With increasing age the hard nucleus includes more and more of the lens substance and is insoluble in the aqueous In patients over 40 it has to be removed en masse Some Anglo-Indian surgeons and a few continental operators extract the lens in its capsule Most ophthalmic surgeons prefer to leave the capsule in the eye, delivering the lens from within it They hold that this is the safer method, with less likelihood of vitreous loss It has the disadvantage that a second operation (needling) is sometimes necessary, to cut a gap through the capsule left in the pupil The steps of the operation are —

(*a*) *Anæsthesia*—Five per cent cocaine drops are instilled at five minutes intervals for 30 minutes

(*b*) The *incision* is made with the narrow Graefe knife by puncture, counter-puncture, and one or two sawing movements It should be placed just outside the corneal margin, and should involve two-fifths of the circumference A small flap of conjunctiva should be left at the top

(*c*) The *capsule* may be divided by the knife as it passes from puncture to counter-puncture during the incision, or it may be divided afterwards by the cystitome

(*d*) *Extraction* of the lens is performed by pressing the lower part of the lens backwards and upwards by means of some blunt instrument such as the back of a lens curette Slight pressure on the posterior lip of the wound assists the upper edge of the lens to tip forward and present The lens is then coaxed out slowly by gradual pressure from below, aided, if need be, by the point of the cystitome above

(*e*) *Iridectomy*—A small portion of iris is next snipped off, leaving the pupillary margin intact (peripheral "button-hole" iridectomy) If a complete iridectomy is desired, it should be made after the incision Many surgeons dispense with iridectomy (simple extraction)

(*f*) By *replacing the iris* with an iris repositor, the pupil is rendered central, and the conjunctival flap is then stroked into position over the wound

The Chief Complications of the Operation

(1) *Loss of Vitreous*—This is serious, although after it many cases regain a vision of 6/18 or 6/12 It gives an added danger of detachment of the retina, which usually results in blindness

(2) *Acute Infection*—This is nowadays rare, and is guarded against by surgical cleanliness, by proper irrigation of the conjunctiva before commencing the operation, and by a preliminary culture of the conjunctival secretion (to exclude the presence of pyogenic micro-organisms) Its occurrence usually necessitates excision or evisceration of the globe

(3) *Prolapse of the Iris*—This may occur during the first 24–48 hours, and for this reason the patient should be kept quite still for the first few days after the operation If it occurs, the prolapse must be cut off as soon as possible As a rule, no permanent harm accrues Prolapse is less likely to take place if an iridectomy has been done

(4) *Capsule Strands in the Wound*—These are impossible to see at the time of operation, and if included in the scar are a source of irritation and secondary glaucoma They are more likely to get caught with complete iridectomy If a simple extraction or one with peripheral iridectomy is done, the capsule gets swept away from the wound by the pupillary margin of the iris, as it is replaced by the iris repositor

After-Care

Both eyes should be bandaged for 24 hours The eye may be examined in 24–48 hours and a drop of warm atropine (1 per cent) instilled The patient should be kept in bed for six or seven days The average length of stay in hospital or home after the operation is 14 days Needling, if necessary, should be performed as soon as the eye is free from congestion

Special Articles.

PENSIONS FOR HOSPITAL OFFICERS AND NURSES.

As was noted last week, at the Sixteenth Annual Meeting and Conference of the British Hospitals Association the proceedings opened with a paper by Mr Herbert L Eason (superintendent of Guy's Hospital, London) describing the movement to provide pensions for hospital servants and giving a critical summary of the scheme now approved by the King Edward's Hospital Fund for London This scheme was set out in THE LANCET of March 27th (p 679) and April 3rd (p 972).

Mr Eason said that the question might not have reached its present stage if it had simply been one of pensions for those employed at individual hospitals, what made coordinated action immediately important to the hospitals themselves was the fact that the present system checked the movement of officials from one to another—whereas migration should be the characteristic feature of a hospital officer's life It had been for this reason that the Whittall Committee had come to the conclusion that a Federated Superannuation Scheme on the lines of the Federated Superannuation Scheme for University Teachers was the proper solution of the problem After considering the varieties of insurance pensions schemes it had rejected all the mutual schemes and decided in favour of the insurance method A conference, at which were representatives of the British Hospitals' Association, the Hospital Officers' Association, the College of Nursing, and the King Edward's Hospital Fund for London, had resulted in the publication in November last of a draft scheme of pensions for hospital officers and nurses This had been submitted to hospitals generally and many of them had been represented at a conference called by the King's Fund in London in May where differences of opinion were discussed On May 14th the Council of the King's Fund had approved, amongst others, the two following resolutions —

1 That, in making annual grants to maintenance to hospitals on its list at the ordinary distribution, the King's Fund should take into account (subject to such conditions as may be approved by the management committee) the amount spent by a hospital on an approved contributory pensions scheme, including amounts spent in respect of existing officers and retired officers

2 That the assistance offered by the King's Fund should be on the following scale—viz , a maximum sum for seven years of £20,000 a year, or 25 per cent of the expenditure of the hospitals on the approved scheme, whichever is the smaller , this amount to be provided as far as possible by means of contributions obtained by a special appeal in selected quarters and to be increased if sufficient funds are realised by such appeal

On June 10th the King's Fund had written to the hospitals which showed sympathy with the proposals, enclosing an outline of the pension scheme as approved by the Fund for the purpose of special grants in aid In its covering letter the Fund stated that it would be glad to know if the hospital in question was prepared to cooperate, and proposed calling a further conference for the purpose early in July It was this scheme, as now modified, approved, and made public by the Fund, that Mr Eason intended to discuss

The Present Proposals

The suggestion was, he said, that the total contribution or premium should be 15 per cent of salary and emoluments (Emoluments included meals, board, and lodging at specified rates) It had been urged that this was too high a premium, but that was purely a matter for actuaries, and the King's Fund, in accordance with hard economic facts, had declined to recognise for purposes of a grant any scheme that envisaged smaller contributions It was proposed that 10 per cent of the contributions were to be paid by the hospital and 5 per cent by the officer or nurse, but the relative proportions might possibly vary in different institutions For officers the policies were to mature at the age of 60 and for nurses at 55 The Scheme was to include all salaried staff, administrative, clerical, or dispensing, whose total of salary and emoluments was over £160, and it was to be compulsory for new entrants into the service of the hospital Where the total remuneration was between £100 and £160 the hospital would have the option of admitting those who wished to join Although no maximum pensionable salary limit was to be laid down it would be open to an individual hospital to arrange with an individual officer that an increase of salary beyond a specified high level should not carry with it any increase in the contributions of either

As was well known, said Mr Eason, male hospital officers were comparatively few in number as compared with the nursing staff, and it was probable that if the pension scheme had referred to hospital officers alone, there would have been much less criticism and much less apprehension as to the financial burden on hospitals in future As a matter of fact, the Scheme as applying to hospital officers had been generally approved, and it had been agreed that if an officer migrated within the hospital service, he should take the benefit of both contributions with him to his next institution; that if he left hospital service altogether within ten years of joining the Scheme, he should take the benefit of his own contributions only; and that if he left hospital service altogether after ten years he should take the benefit of both contributions Policies were to be taken out with insurance companies and the officer or nurse was to have the choice of alternative benefits—e g, endowment assurance policies with profits or deferred annuity policies

Nurses' Pensions

Mr Eason then proceeded to discuss the Scheme as it affects nurses It was, he said, to include all female professional nurses, whether nursing the sick or doing work under a public authority, and it was to be compulsory for new entrants to a hospital's service to join it or continue membership if already members The complete scheme included all probationers after one year's training, but it would be open to each hospital to decide whether to admit them then or only after their names were placed on the State Register It was over the question of nurses' pensions that there had been most discussion, but the attitude of the nurses' representatives had been quite definite The College of Nursing urged that the nurse's life was a short one Often she did not begin her career till the age of 20 or later, and she was worn out and should become pensionable at the age of 55 Her pension would be smaller than that of the hospital officer because her active career was shorter and because female annuitants lived longer than male The representatives of the nurses therefore asked that contributions towards nurses' pensions should begin as early as possible, and suggested that hospitals and probationers should begin their payments as soon as the probationer started training

Objection to this, continued Mr Eason, might be taken on three grounds (1) That a contribution of 10 per cent on salary plus emoluments for every nurse during the whole period of her training imposes too great a burden on the hospital, (2) that a contribution of 5 per cent is too much for the nurse to pay, and (3) that there is no claim on the hospitals to contribute in respect of pensions for probationers as they are only students in training As regards the first objection every hospital should calculate for itself what would be the total cost of premiums in respect of its whole nursing staff, and then convert this cost into a percentage of the annual expenditure of the hospital He had estimated that if Guy's Hospital were to make these 10 per cent contributions in respect of every hospital officer eligible under the Scheme, and every probationer, trained nurse, sister, or member of the female administrative staff, the total cost of the premiums would be between 2 5 and 3 per cent of the hospital's annual expenditure, and he could not help thinking that the public—upon whom the hospitals really depended for support—would not consider 3 per cent of the total annual expenditure an excessive amount to pay towards the pensions of those who were, in fact, doing the greater part of the hospital work, excluding the medical service At the present time there was difficulty in obtaining probationers in hospitals, and it might be worth while to consider which in the long run would be more expensive—to pay pension premiums for nurses in training, or to run short of probationers and be obliged to staff the hospital with trained nurses The second objection, that it was impossible for a probationer in training to afford the 5 per cent of her salary and emoluments, was a dangerous argument to use, since the immediate inference to be drawn was that the probationer is paid an inadequate salary If attempts were made to justify this inadequacy on the ground that nurses receive their training and are paid for it as well, this argument would immediately be met with the retort that in return for her training the probationer does about 80 or 90 per cent of the hospital's nursing work and thereby saves the hospital large sums of money. As long as she was doing this, he thought it almost impossible to justify a salary inadequate for the payment of the nurse's contributions towards her pension The representatives of the nurses had also pointed out that at no period of her life would the nurse be in such a favourable position to pay her own premiums; as a probationer her financial needs were practically limited to clothes to wear outside the hospital Personally, Mr Eason felt that early contributions by hospitals towards nurses' pensions would be one of the strongest inducements to women to take up nursing as a profession

Details and Difficulties

Other questions, he continued, arose in connexion with nurses' pensions When should they commence? After how many years' service should a nurse be entitled to carry away both her own and the hospital's contributions? Probably few hospitals would agree to start the premiums immediately a probationer entered the hospital service, as it was a matter of common experience that many nurses left during their first year If, however, a nurse settled down at a hospital for a year, there was a strong presumption that she would complete her training, and he thought, therefore, that hospitals would be well advised to commence premiums at the end of the first year of training The question when a nurse should be entitled to carry off both her own and the hospital's contributions required careful consideration From figures of one London hospital it appeared that out of 500 consecutive nurses who joined the hospital, nearly 40 per cent were married ten years after they had entered As a matter of fact, the great majority of nurses who married did so within five years or so of leaving the hospital, and it was suggested, therefore, that all contributions should be held in reserve or in trust by the hospital until the nurse had been five years in the practice of nursing, after she had completed her training, until then the hospital would retain its own contributions and she would be entitled to take away only her own If, after five years, the nurse was still nursing, whether in an institution or in private nursing, the hospital would assign to her, or whatever organisation was acting as her trustee, both her own and the hospital's contributions

Hospital governors might also say What concern is it of ours to start making contributions towards the pensions of our probationers, the great majority of whom, at the end of their training, will leave the hospital and will never be seen by us again? The answer to that question was that it does not matter to the hospital what happens to the nurse after she has left it The contributions made by the hospital while she was in training or while serving the hospital as a trained nurse would provide her with a certain pension at her retiring age, which pension would, of course, be in addition to any pension to which she might be entitled should she join any other service which provided a pension It should be remembered that nursing was a very arduous profession—that a number of nurses broke down during their nursing career—and that at the end of their nursing life many nurses were at the present day in absolute want Of all appeals to the charitable public a claim for additional support for the purpose of providing pensions for nurses would, he believed, meet with the readiest response

It must not be forgotten also that in London at any rate, the King's Fund had stated that it was prepared to make a grant up to 25 per cent , not only towards the premiums for pensions for hospital officers and nurses who would in future join the scheme, should the hospital participate, but also in respect of pensions already being granted by the hospitals, and of those which might in future be granted by the hospitals to those hospital officers and nurses who, by reason of seniority and length of service, were ineligible to join the present scheme

---

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

LAYING OF THE FOUNDATION-STONE

In 1921 a committee was appointed by the then Minister of Health, with the Earl of Athlone as chairman, "to investigate the needs of medical practitioners and other graduates for further education in medicine in London, and to submit proposals for a practicable scheme for meeting them"

This committee made two main recommendations one for the development of the work of post-graduate medical education generally in London, and the other for the setting up of what they called an Institute of State Medicine, to be established by the University of London, in which instruction should be given in public health The latter recommendation happily synchronised with proposals which the Rockefeller Foundation had in mind for establishing in London a great school of Hygiene and Tropical Medicine They were impressed with the needs of the situation as set out in the Athlone Committee's report, and they made their now well-known offer of two million dollars to the British Government for the building and equipment of such a school This offer was accepted and the Government assumed the necessary responsibility for the school's adequate maintenance when it was completed

The London School of Hygiene and Tropical Medicine was established by Royal Charter in 1924, and the old London School of Tropical Medicine was taken over in August of that year

In 1925, after a limited competition, Mr P Morley Horder and Mr Verner O Rees were appointed the architects of the new building, the foundation-stone of which was laid by the Minister of Health on Wednesday, July 7th, 1926 The elevation drawing of the building which is to be erected (see illustration) shows that it will be a notable addition to the public buildings of the metropolis

The Scope of the Institute

In the construction of the building certain requirements had to be met which, together with the extent and form of the site and the funds available, determined the architectural form which the school is to assume

Provision had to be made for teaching hygiene in all its branches for instruction in tropical medicine, and for research work in both these subjects, and in any of the ancillary sciences The balance had to be maintained equally between teaching and research Both have received sympathetic consideration As a result, it was finally decided to provide for research one-sixth of the total space available for instructional purposes This is a liberal allowance when it is remembered that the space devoted to teaching includes a big lecture theatre, numerous roomy class rooms and general laboratories, together with the library, a very large museum on two floors, tutorial rooms, and other accommodation The number of students which the school is intended to accommodate is 250 Of these, it is considered that 100 will be engaged upon the study of tropical medicine, a figure based on the present attendance at the course given in the tropical division at Endsleigh-gardens, where there has of late been an average of nearly 70 per session The remaining figure, 150, representing students studying for diplomas or degrees in public health, has intentionally been placed very much on the safe side At present there are only about 45 students attending courses in London for the diploma in public health, but it is noteworthy that a recovery has taken place from the marked fall in numbers which followed the introduction of the new regulations of the General Medical Council, and there can be no doubt that this increase will continue, although it may be many years before there are as many as 150 aspirants for a public health qualification

The building, of which the foundations have been laid while a start has been made upon the steel structure, will be situated between Gower-street and Malet-street, behind the British Museum It will front south upon Keppel-street, and it is hoped that at least the frontage, which contains the main entrance will be of Portland stone This Keppel-street elevation will be enriched by a wide fringe composed of wreaths and of the names of some of the great pioneers in hygiene and in tropical medicine Finality has not yet been reached as regards these names Over the main entrance there will be a large panel on which the handsome and interesting seal of the school will be engraved The general shape of the building is that of a letter H, with the Keppel-street front closing the southern end of the H, and the crossbar dividing the enclosed space into two nearly equal courts, one of which, the northern, is not encroached upon, while the other, the southern, is partly occupied by the lecture theatre This arrangement provides a building singularly well ventilated by natural means and well lighted, while it will be easy to find one's way about it, especially in view of the manner in which the different sections are grouped

The provisional scheme of studies provides for six main divisions—namely, those of applied physics, physiology and principles of hygiene, chemistry and biochemistry, immunology and bacteriology, medical zoology, including parasitology and comparative pathology, epidemiology and statistics, and, finally, the principles and practice of preventive medicine, general sanitation and administration This grouping has been retained but, in addition, there has been recognition of the fact that the clinical pathology of exotic diseases forms a most important part of tropical medicine and, accordingly, as will be seen, a special laboratory has been devoted to the joint needs of this subject and of certain branches of tropical hygiene with which, of course, tropical pathology is intimately associated

It has been decided subject to satisfactory estimates of cost, to warm the building by the panel system of heating This is a modification of the old Roman hypocaust method and has many advantages while its disadvantages and difficulties can, it is believed, now be discounted

Basement —The basement, which is really a half basement, contains the lower floor of the lecture theatre, provision for museum storage, library and publications stock rooms, goods reception store, and issue rooms, together with carpenters' and metal workers' shops Here also will be found the X ray department and the photographic unit, the distilling room, the room for large centrifuges, A spacious post-mortem room is being provided It is hoped here to conduct autopsies upon animals dying in the Zoological Gardens which often exhibit the lesions of diseases met with in the tropics At present the School is in close touch with the Zoological Society of London, a member of its staff being pathologist to that Society The lecture theatre has accommodation for 250 students Behind it are the lecturers' room and the preparation room. From the latter, cinema epidiascope and lantern work will be conducted. Special attention has been paid to the question of acoustics, the elimination of draughts, adequate lighting, and facilities for rendering the theatre dark.

Ground Floor.—The main entrance on Keppel-street leads into a fine entrance hall, from which there is direct access to the lecture theatre. The whole of the front block, facing Keppel-street, with the exception of the Gower-street corner, is utilised for purposes of general administration, the board room receiving special architectural treatment as it will be panelled in oak and ebony. The Gower-street corner houses the professors' common room and writing room. The eastern wing of this floor, facing Malet-street, contains, from south to north, the director's laboratory and a laboratory of sanitary engineering which is intended to be partly a classroom wherein students studying public health will be taught to read and perhaps to prepare plans, will become conversant with the principles of town-planning and will work with rough models of filters and other sanitary appliances with which they should have some acquaintance. In the crossbar facing north, and thus assured of good lighting, is the laboratory of tropical hygiene, already mentioned, wherein the clinical pathology of the tropics will also be taught. The western wing of the ground floor, facing Gower-street, contains common rooms for the professors and men and women students, and a convenient room for the service of tea and light refreshments. At the north end is a large students' study room, where silence will be enforced. Provision is also made on this floor for the classrooms, for the Division of General Sanitation and Public Health. The student in this division will get a great deal of his instruction outside from medical officers of health, both in urban and rural districts.

First Floor.—The library, which will be a large and imposing room 33 feet wide and 120 feet long, is given the place of honour in the front of the building. To its left front lie the offices of the Bureau of Hygiene and Tropical Diseases, which it is proposed should continue, as at present, a tenant of the School. It is indeed possible that a closer association will eventually develop. Immediately behind the library access is provided to the flat roof of the lecture theatre, which will be laid out as a garden court. The west end of the library is bounded by an ample periodicals room, for it is intended that the current literature shall be separately housed and made readily available for consultation. This room communicates with the library and both can be thrown open, together with the above-mentioned roof-garden, on the occasion of large social or scientific gatherings. The rest of this, the west wing, is entirely occupied by the Division of Epidemiology and Statistics and contains a laboratory, card-index room, study rooms, and staff quarters. The whole of the crossbar of the H is devoted to the Division of Applied Physiology, as is the northern half of the east wing of the building. This division is likely to be closely concerned with the problems of industrial hygiene and so, in addition to the X ray department and constant temperature room in the basement, it is provided with a large cross-lighted laboratory, a range of fine research rooms, mostly facing north, a gas room, and a gas chamber.

Second Floor.—Here the lower storey of the museum, which will be devoted to hygiene, runs the whole length of the Keppel-street front. In the roof there are three open wells admitting light from above, while it is well lit on the south by windows looking out on Keppel-street and less fully on the north by windows overlooking the north court. There should, however, be ample daylight illumination, and it is important to secure as much wall space as possible. The museum has been granted 15,000 feet of floor space, but in all probability, this will eventually be found insufficient to illustrate adequately the wide subjects with which it will be concerned.

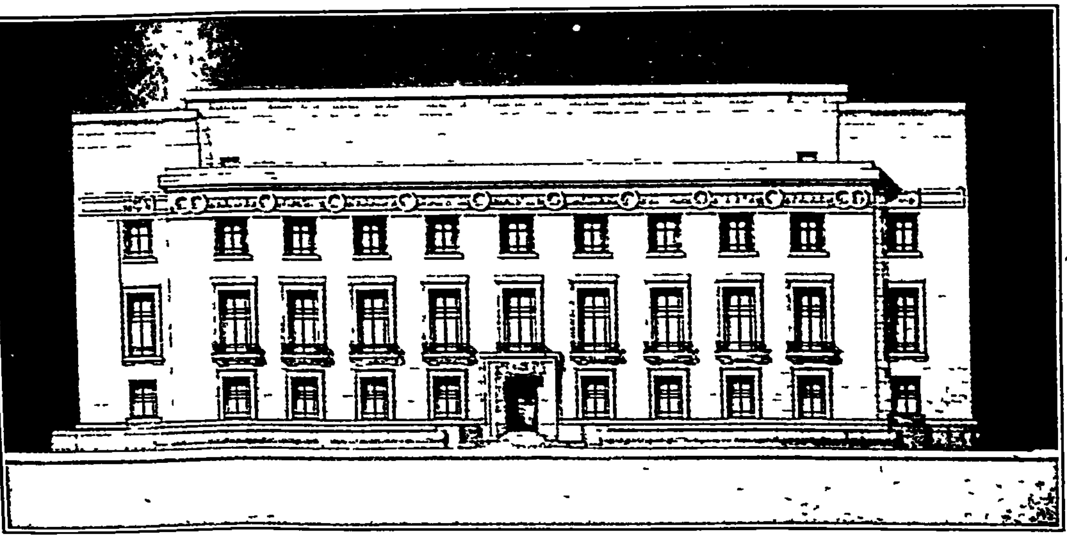
The rest of this floor is divided between the division of chemistry and biochemistry and that of bacteriology and immunology. The latter has been given the larger share, for there are likely to be more research workers in bacteriology, but there is no great difference in the space allocated to each.

The large laboratory of the Chemical Division in the north-east corner of the building will accommodate 70 students and the biochemical and nutritional laboratory will take 35. It is hoped that special instruction will be given on the subject of nutrition and that research will be carried out, not only on the nutritional value of foodstuffs, but on their money-value. The biochemist must have his experimental animals alongside him, so a roomy and well-ventilated animal house has been sandwiched in between the biochemical laboratory and the museum. The chemical department has its quota of staff and research rooms and a fine classroom with 90 seats.

The chief feature of the Division of Bacteriology and Immunology is the large bacteriological laboratory which can hold 90 students and has cross lighting and ventilation. There are smaller general laboratories in this division, which also contains a good-sized classroom, media, sterilising and washing-up rooms, hot and cold incubator chambers, research laboratories, and a dark room.

Third Floor.—The upper storey of the museum, which will be devoted to tropical medicine and hygiene, runs the whole length of the Keppel-street front and has roof lighting, which, as stated, is communicated to the lower storey by three open wells in the floor. In close touch with this part of the museum are the museum offices and preparation rooms in the west wing. The rest of the floor is wholly given up to the important Division of Medical Biology, and will accordingly absorb the greater part of the work of the old London School of Tropical Medicine, now continued at Endsleigh-gardens as the tropical division of the present School. The large laboratory for this division has provision for 86 students; in addition to cross-lighting, it has a weaver roof. Other rooms which will be shared by the four departments constituting this division are the two large classrooms, the preparation room, the seminar room, the advanced demonstration room, the reading and reprint room, and the insectarium and aquarium.

The greater part of the space will be distributed between the departments of helminthology, comparative pathology, protozoology and entomology. There are some special features, such as a joint dissecting room for helminthology and comparative pathology, a room for housing the helmintho-



The new home of the London School of Hygiene and Tropical Medicine.
(Main elevation—Keppel street front.)

logical collections, a fæces room, adequately ventilated, and a stock room for entomological specimens.

Fourth Floor—This is a recessed floor, occupying only the crossbar of the H and the southern portion of the Gower-street front. Here are the caretaker's quarters, the artist's room, the cinema preparation room, and also the animal quarters, with exercise court and all conveniences. From the artist's room there runs south a special range of mice quarters.

Fifth Floor—This is represented by additional accommodation for animals and provision for water tanks and fan chambers. Like the fourth floor, it is recessed from the wall-line of the main building and is of no great extent.

It will be obvious that the structure of the building has been most carefully planned. The design has proved readily adaptable to all the varied and exacting requirements of the several divisions of work, and it may be anticipated that the completed edifice will worthily carry out the intentions of the promoters and the generous conception of the Rockefeller Foundation. It is unfortunate that representatives of the Foundation were unable to be present at the ceremony to hear from the chairman of the board, Sir Alfred Mond, or from the Minister of Health, an expression of the appreciation of the British people of this recognition of London as a fitting centre for a great school of preventive medicine.

MEDICINE AND THE LAW

The Judicial Value of Technical Assessors

MEDICINE and seamanship have this much in common that professional experts in both sciences are called in as assessors in courts of law. There is this difference that, except perhaps in workmen's compensation cases, the common law courts get almost all their technical guidance in medical matters from expert witnesses rather than from assessors, whereas the Admiralty courts rely more upon assessors than upon expert witnesses. But in either case, once an assessor is called in, his legal position and authority are the same whether he is a medical or a nautical expert. The medical profession, therefore, may be interested in a recent House of Lords appeal (the *Australia*) where the divergent views of the experts evidently baffled the judges. The President of the Admiralty Court got an answer from his assessors upon which he held a vessel called the *Nautilus* to blame for a collision with the *Australia*. The Court of Appeal was inclined to agree till it got a directly opposite answer from its own assessors; feeling obliged to give effect to this, it reversed the President's decision. The House of Lords in turn consulted its own assessors whose opinion was not exactly unanimous, and reversed the judgment of the Court of Appeal. The dilemma was not unlike that in a case tried in 1919 (the *Melanie*) where Mr. Justice Hill's findings were approved by his assessors, the Court of Appeal followed its own assessors' advice, and finally the House of Lords was distracted by the fact that its two assessors expressed diametrically opposite opinions on each point of substance. Doctors proverbially differ; sailors, it seems, can differ just as widely.

The result of these differences is two fold. Firstly, Lord Dunedin, in the *Australia* case, tells the Court of Appeal not to think that its assessors are of higher authority than those of the court below. Appeals are from judge to judge, not from assessor to assessor. "There is no hierarchy of assessors." Lord Sumner added that the technical advice given below is available for the consideration of the appellate tribunal as well as that given by its own assessors; the latter are not substituted for those previously consulted; they are additional to them. The second and more general result is that the courts grow more ready to dispense with all expert guidance if the experts' views are so discordant. Assessors, said Lord Dunedin, occupy much the same position as do skilled witnesses except that they are not brought forward as the partisans of one side or the other. Just as in patent cases a judge must make his own choice between two opposing opinions on a technical matter, so the court must make its own choice if assessors disagree. He deprecated questions being put to assessors in a form tantamount to asking them if they would find for the plaintiff or the defendant. Lord Sumner repeated that the court cannot surrender to assessors the judicial function of deciding the issue, however technical it may be. "Authority for the proposition that assessors only give advice, and that judges need not take it but must in any case settle the decision and bear the responsibility, is both copious and old. . . . After all, experience at sea is not everything. Assessors are not chosen for their personal conversance with collisions, and an experienced judge or counsel may boast that he has, in a sense, been in hundreds of collisions while the assessors have hardly seen tens."

Altogether these two cases, the *Melanie* and the *Australia*, have led the law courts for the moment a long way in the direction of discounting the value of the expert's guidance. The court of first instance, said Lord Birkenhead in the former, will naturally be in frequent and informal consultation with its assessors, the Court of Appeal can probably ask its own assessors definite written questions, and then perhaps the House of Lords will not want assessors at all. "Personally," said Lord Dunedin in the more recent case, "except for the purpose of explanation, I shall always ask an assessor as little as possible." He goes on to hint that many technical niceties disappeared when sailing vessels gave way to steamships and that seamanship in avoiding a collision is often a question of common sense. In the light of such observations, medical assessors and experts should perhaps prepare themselves for signs of a judicial revolt against technical leading-strings.

A Claim for Fees.

A recent action in the Bromley County Court illustrates the uncertainty of remuneration for services rendered by practitioners. Dr. Alfred Tennyson-Smith, of Orpington, attended the two daughters of Mr. F. H. Fletcher, a merchant, of St. Mary Cray, in April, 1924. On the 25th of that month he was called to Mr. Fletcher's house at 11 P.M. and found one of the daughters gravely ill, the cause being acute appendicitis and acute peritonitis. An immediate operation being deemed necessary, the child was removed with her father's consent to the Cray Valley Hospital. The operation was performed in a private ward and was completely successful. Dr. Tennyson-Smith had an assistant and an anæsthetist; he also had vaccine prepared, and he paid 28 visits to the child after operation. He afterwards sent in an account for £81, including an operation fee of 50 guineas. On Mr. Fletcher's complaint of the size of the bill, he reduced the operation fee from 50 to 35 guineas to save further trouble and to obtain a settlement. From the account of the county court proceedings in the *Sidcup Times* it appears that adequate evidence was placed before the court to show that the fees charged were reasonable. On the other hand, for the defendant, a nursing-home proprietor in London was called who declared the operation fee excessive. A reasonable charge, in the opinion of this witness, would have been 25 guineas for the surgeon, 10 guineas extra if he had an assistant, and 5 guineas for the anæsthetist, with no extras for visits. His Honour Judge Parry seems to have accepted this standard as he gave judgment for the plaintiff for £42 4*s.* 6*d.* The judge remarked that it was an unfortunate dispute and that it was a pity that the parties could not have met to discuss the matter; he added that the defendant owed a very great debt of gratitude to the plaintiff for the skilful way in which he dealt with the case. So far as can be judged from the newspaper report of the evidence, the defendant had been anxious to have a London surgeon to operate but was told—no doubt correctly—that there was no time Mr Fletcher appears to have resisted Dr Tennyson-Smith's claim the more tenaciously because there was also a bill of some £35 from the hospital, and, in addition, he had had the expense of a nurse for the child for three weeks

The case should not be taken as standardising the fee for an operation for appendicitis at 25 guineas The law courts will take the circumstances of a particular case into account, including the means of the defendant and the professional status of the plaintiff All that this case decides is that in a particular set of circumstances a county court judge thought he could accept the statement of a witness to the effect that there were many excellent surgeons who would be quite willing to perform the operation which was necessary for the successful treatment of the defendant's daughter for a fee of 25 guineas That statement could be much challenged.

Reponsibility for Post-mortem Examinations in Hospitals

According to the *Tunbridge Wells Advertiser* some difference of opinion has arisen locally between the coroner and the staff of the General Hospital The coroner (Mr A H Neve) has stated at recent inquests that his invariable rule was that the medical practitioner who has been in constant attendance upon a patient should continue in charge of a case for the purpose of giving evidence as to the cause of death The hospital authorities, as a matter of principle, maintained that where a man is brought into hospital and his case is diagnosed there, the house surgeon should perform the post-mortem examination (if one should be necessary) and not a practitioner from outside To this the coroner rejoined that he has no statutory authority to pay fees to two doctors unless it is impossible to ascertain the cause of death from one He added that inquests were held by arrangement at the hospital and that the hospital received good fees, so that he was himself under no obligation to the hospital or its staff, the arrangement being one of which there was no reason to complain It seems that the coroner had threatened, on somewhat insufficient ground, that, in the event of any dispute, he would call in the medical officer of the borough to make the post-mortem and give evidence as to the cause of death This course he justified on the ground that the medical officer was also the police surgeon and that, where there was no doctor concerned, the police would call him in Against such a step the house surgeon naturally protested , in his view, if a patient dies in the hospital, the hospital authorities should make the post-mortem examination and receive the fee The coroner, however, reiterated his rule that, when a practitioner has been in attendance on a patient, he shall be called to make the post-mortem and give evidence In certain cases, of course, the coroner has to certify that the deceased was not attended by a medical officer in the institution In the particular case which gave rise to the discussion, the deceased had been for some weeks mentally unstable, so that the coroner could with good reason maintain that the patient's own practitioner was the best possible witness of his recent state of health This local dispute, if such it may be called, will no doubt be amicably settled with some common-sense reconciliation of two different points of view On the one hand, the coroner must have before him the best possible evidence of the cause of death, for which purpose the testimony of any practitioner who has recently attended the deceased will be particularly valuable , if any statutory restriction as to fees prevents the coroner from obtaining the fullest information, the law should be altered On the other hand, the reasonable rights of hospitals should be respected, and any observation which can be construed as a possible threat of interference with hospital administration by outside officials should be avoided

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

TWELFTH ANNUAL CONFERENCE

This conference was held in the McLellan Galleries' Glasgow, on July 1st, 2nd, and 3rd, and was attended by over 200 medical men and representatives of the local authorities from all parts of the United Kingdom and Ireland

Sir Arthur Stanley (chairman of the Council), presided at the opening session In introducing the Lord Provost (Sir W W Montgomery), who welcomed the delegates to the city on behalf of the Municipality, he said that the work of the Association was mainly one of propaganda, of obtaining facts relative to tuberculosis, and giving those out to the general public A fortnight hence, he stated, an appeal for £100,000 was to be inaugurated at a meeting at the Mansion House, London, over which the Prince of Wales would preside The £100,000 was to be utilised (1) to educate the masses regarding the causes and prevention of tuberculosis by means of lectures, acting in cooperation with recognised authorities and medical practitioners throughout the country , (2) to render immediate help to applicants, where the machinery of Governmental organisations could be employed , (3) to devise and develop practical schemes for tuberculosis care committees, the pressing need for which had been emphasised by the Ministry of Health

Dr A. S MacGregor (medical officer of health, Glasgow) introduced a discussion on

Provision for the Care of Non-Pulmonary Tuberculosis

He dealt with the question as to what extent administration had fallen short of providing the necessary facilities for each area, and what form these facilities should take Prolonged treatment of non-pulmonary forms of the disease was essential, and that in specially designed and equipped institutions Until recently the results had been greatly marred by the arrival of the cases at a late stage of the disease Advanced disease implied destruction of bone, and that frequently led to permanent crippling and deformity More recently cases had been obtained at an earlier stage and better results had followed Commenting on the work at Robroyston Hospital, Glasgow, he pointed out that in the treatment of spinal tuberculosis in 1925, 52 per cent of the cases had been dismissed with the disease arrested, as compared with 34 per cent in 1922–23 In hip-joint disease the hospital reports showed an increase to 61 per cent of patients discharged with the disease arrested In those, partial or complete restoration of function had been the rule At the present time the corporation of Glasgow have approximately 436 beds available for the treatment of non-pulmonary tuberculosis That was not sufficient, and the corporation had decided to increase the accommodation at Robroyston In addition they were building at Mearnskirk a sanatorium for 330 cases of non-pulmonary tuberculosis in childhood. This would increase their accommodation to 750, and would mean a bed for every 1300 of the population That, he thought, would be sufficient for the necessities of the case on the institutional side He had been much impressed with the results obtained in the reduction of crippling due to tuberculosis, and looked forward to the day when it would entirely disappear

Dr James Taylor (consulting surgeon, Glasgow Corporation hospitals and sanatoria) dealt with the clinical aspect of non-pulmonary tuberculosis He stated that for effective work five things were necessary (1) Prompt recognition of the disease , (2) special open-air hospitals on the lines of Rollier's institution at Leysin, or the institutions at Berck-Plage , (3) the equipment that would enable special treatment to be given, such as plaster, celluloid, or certalmid splinting, light treatment, and X rays, &c , (4) prolonged treatment, if necessary, over a term of years , (5) efficient after-care, best carried out at special tuberculosis dispensaries. He emphasised that the improving of housing conditions and the provision of abundant air and sunshine for the population generally, although it would entail a great initial expenditure, would cut down quickly the sum spent yearly on the maintenance of special institutions for treatment of tuberculosis.

Dr. James Johnstone (medical superintendent, Heatherwood Hospital, Ascot) gave figures relating to the cases admitted to this institution since 1922. Only 45 per cent. out of a total of 251 had had the disease for less than one year's duration before applying. Before being admitted these cases had to wait for an average period of six and a half months, mostly receiving some form of treatment in the meantime. The efficacy of that treatment could best be judged by the condition of the patients on admission. This was far from satisfactory. He stressed (1) The importance of looking on surgical tuberculosis as a local manifestation of a general infection; (2) the importance of an intimate knowledge of the patient and his environment in guiding treatment; (3) the importance of continuity in dealing with cases. For this the National Scheme of the General Committee for Care of Cripples was to be commended. According to this each authority or group of authorities should have their own special hospital in charge of a competent orthopædic surgeon. Combined with this there should be a system of clinics in outlying districts, with specially trained after-care orthopædic nurses. There would thus be a great network of special hospitals throughout the country whose staffs would be in close contact with the areas served. These, through the clinics, would provide an efficient organisation for diagnosis and after-care. He was certain that the need could not be met by large national hospitals.

Dr. J. H. Paul (Millport) explained in detail the working of a voluntary institution for surgical tuberculosis, dealing with the St. Andrew's Home, Millport, where there are 35 beds approved by the Scottish Board of Health for such cases. He had proved that real open-air treatment was possible in winter as in summer in unheated wards in Scotland. An X ray apparatus and mercury-vapour lamp had been installed, and bone tuberculosis of all types was being dealt with on conservative lines.

Dr. W. B. Knobel said that in London a child with surgical tuberculosis was not kept waiting a single day. The County Council held that affected children should be under expert treatment at the earliest possible moment. Unfortunately they could not get early cases except in a small proportion.

Dr. Marsden (Bethnal Green, London) said that this was the only form of infectious disease which was not treated as if it were infectious. No genuine results could be anticipated as long as the problem of overcrowding was allowed to remain unsolved. The whole work of the Association, he declared, was a farce unless housing was dealt with.

Sir Robert Philip (Edinburgh University) reminded the conference that this disease was not confined to the poor; it prevailed all over the world, among high and low. The disease began like a weed, and like a weed in the garden if it were taken in its early stage it could be rooted out.

The afternoon session of the first day of the conference was devoted to the subject of the

Actual Place and Function of the Tuberculosis Dispensary in the Tuberculosis Scheme

Sir Arthur Stanley again presided.

Sir Robert Philip said that the principles which had been effectively applied in relation to other infective conditions, with appropriate modifications, were applicable to tuberculosis. The tuberculosis dispensary had demonstrated the extensive ramifications of tuberculosis and collected proof of the universality of tuberculosis throughout the community. It had afforded incontrovertible evidence of the spread of infection through a household from a primary source. By getting at the cases in the earliest stage it had rendered possible the practice of anticipatory treatment, which has in view the raising of the resistance of the individual, antigenic or otherwise. Observation at the dispensary of the varying manifestations of the tuberculosis process throughout a long series of years had shown that a patient in the so-called third stage with cavity formation (regarded by many as the terminal picture) could go on comparatively fit and well for 30 years or longer. By continued observation on ambulant patients it had proved how essential was the maintenance of such supervision and how valueless the result of short periods of residential treatment. By domiciliary visitation it had succeeded in reducing the effects of unhealthy environment and re-creating insanitary houses after the image of the sanatorium. The dispensary's educational value could hardly be over-estimated. Unfortunately the ideals of the dispensary and its great possibilities were not being realised everywhere. It was common to find the tuberculosis dispensary concerned solely or chiefly with cases of pulmonary tuberculosis, although those constituted for the most part a later manifestation of the disease. The idea of using the pronounced case of infection as a clue to the earlier was overlooked or ignored.

Dr. G. Lissant Cox (central tuberculosis officer, Lancashire) discussed two important functions of the dispensary—diagnosis and prevention. In regard to diagnosis, in the county of Lancashire they had five large dispensary areas, with an average population of 350,000. Each area was in charge of a whole-time consultant. To assist those consultants there were eight assistant tuberculosis officers and 30 health visitors. The consultants in addition acted as visiting medical superintendents of pulmonary hospitals, and were paid from £950 to £1150 per annum. Each consultant had his own laboratory and trained laboratory workers and his own X ray apparatus. Dr. Cox attached great importance to having, for diagnosis, a real specialist with his own laboratory, X ray plant, and observation beds in a hospital. As to prevention, in the past too much emphasis had been laid on treatment rather than prevention. He could even remember being warned that if he did not make better provision for treatment—that was handing out bottles of cod-liver oil—they might not earn the Government grant for their scheme. To illustrate the preventive function of the work he said that the cordial relations existing between dispensary staff and practitioners resulted in a great increase in the notifications of cases of tuberculosis. The non-notified cases fell from 303 in 1918 to 66 in 1925. When infective pulmonary cases lived at home the dispensary staff made efforts to secure for the patient a separate bed. Necessitous cases could obtain these on loan from the county council. As a result of their efforts the deaths from tuberculosis in Lancashire had decreased from 107 per 100,000 in 1918 to 67 in 1925.

Dr. Knobel said the question was whether they were satisfied that under the present dispensary system they were detecting the greatest possible number of cases in the early stage of the disease. Comprehensive schemes had been built up, yet after years of work and propaganda 75 per cent. of the cases were in a more or less advanced or irremediable stage when they first came under the scheme. He regarded that as a serious criticism of the dispensary scheme, so serious that it became a question as to whether dispensaries were or were not organised on the right lines. If dispensaries failed to get hold of more than a small proportion of remediable or curable cases, then the money spent on sanatoriums was largely wasted. He suggested that the Association might consider the advisability of pressing the Government to make provision in the new Factory Bill before them for closer cooperation between factory surgeons and the tuberculosis dispensary, in order to enable them to get at the young adult type of case earlier. He also suggested the desirability of propaganda distinguishing between infective and *non-infective* cases.

Dr. **BRAND** (Clerkenwell) stated that the dispensary was an indispensable instrument in dealing with tuberculosis and should be properly organised as a centre of diagnosis. Practitioners were the potential backbone of the dispensary; with their cooperation the question of the diagnosis of contact cases was relatively simple. He urged county councils, by providing the necessary equipment and giving sufficient study leave, to make their tuberculosis dispensaries more efficient instruments than they had hitherto proved.

Dr. J. **CROCKET** (Bridge of Weir) called attention to the fact that the greatest fall in the death-rate from tuberculosis had taken place before any tuberculosis scheme was conceived. In Scotland the rate per 100,000 had fallen no less than 64 during the 12 years previous to the discovery of the tubercle bacillus in 1881. It had not fallen nearly so much in any 12-year period since. Tuberculosis was a secondary product, and best results would follow from dealing with the contributory factors in its production. Tuberculosis was due to dirt, damp, drink, and bad houses. The carrying out of Public Health Acts and of factory legislation had produced the great fall in the death-rate in the past. More thorough enforcing of the provision of those Acts would do much to cut it down still further in the future. The dispensary was an attempt to accomplish the impossible. Approximately 470,000 died of tuberculosis each year. That implied 470,000 cases of active disease and a further 470,000 potential cases. 420 tuberculosis officers could not effectively supervise home conditions, search out incipient contacts, sort out cases for treatment, give domiciliary treatment, and attend to after-care, in addition to filling up innumerable forms and compiling statistics. Dr. Crocket thought that the practitioner should be trained to do this work, being provided with such consultation service as was necessary. He protested against the present tendency to side-track the medical officer of health and have him do the legitimate work of the family physician. The main work of the medical officer of health should be to deal radically with the great causative factors in the production of the disease.

Dr. **MCCALLUM LANG** (Lanark) spoke about the difficulty in getting adolescents to come to the dispensary for diagnosis; of those who did present themselves for diagnosis less than half were found to be tuberculous. The dispensary thus prevented over-notification of tuberculosis. He thought the part played by the dispensary in the examination of contacts was over-rated.

On the second day of the conference Sir **ROBERT PHILIP** occupied the chair. Prof. **CARL BROWNING** read a paper on

Experimental Studies in Tuberculosis in Reference to the Origin of Pulmonary Tuberculosis.

He proposed to deal only with causation, since this formed the basis of measures aiming at prevention. Practically everyone in a city was liable to breathe air containing tubercle bacilli. Only a minority of those who at some time had harboured tubercle bacilli developed the disease. The objection to the view that adult tuberculosis is a development of infantile disease was that in childhood the causative organism is frequently the bovine organism, and in adult years it is practically always the human organism. The tuberculin test showed the disease to be endemic in European countries. In rural districts in countries such as India this was not so. There natives on exposure rapidly acquired and succumbed to a galloping form of the disease. Endemic tuberculosis and a mild bovine infection in childhood exercised a favourable influence, conferring partial protection. Tuberculosis of the lungs did not necessarily indicate the route of infection, but was evidence of a special predilection of the lungs for the tubercle bacilli. Among mice inoculated intraperitoneally with the human tubercle bacillus 6 per cent. showed massive broncho-pneumonic patches. Of those inoculated with the bovine strain 9 per cent. showed a similar lesion. When infected through the food 11 out of 20 animals showed pulmonary disease, and in 9 the lungs were the only organs affected. Experimental work showed that when infection is passed directly from animal to animal the virulence varies irregularly. As the result of a sojourn in one individual the organism might become highly virulent for others, although it might not produce severe disease in that individual. In the future it might become necessary to utilise methods of prophylactic immunisation to protect the population. As to a practical means of doing this, little was as yet definitely known, though Calmette and his co-workers claimed a considerable degree of success.

Dr. J. A. **WILSON** (Glasgow) read a paper on the

Age Factor in the Incidence of Tuberculosis.

The work for this paper was done on a population 79 per cent. of whom resided in houses of one or two apartments. The patients numbered 3817—1937 males and 1880 females. Statistics for tuberculosis based on the age at death were misleading. They gave an erroneous impression of the age distribution. The expectation of life from the date of sickening was calculated from tables compiled. For many years a decline in the death-rate has been recorded. Coincident with this there had been a change in the age distribution. This might be due to a higher standard of diagnosis. Under 5 years of age the expectation was low. The characteristic disease here was broncho-pneumonia or acute miliary tuberculosis. These were rapidly fatal. From 6–20 years of age the expectation of life was materially increased. The expectation figure one year after the onset was lower than the corresponding figure in the younger group. From 21–40 the expectation was better in both sexes. Fewer acute cases died within six months. The tendency to chronicity was more marked in the males. Over 41 the expectation was diminished. The figure in males was lower than that for the 6–20 group. At all ages the expectation of life was less for the female than the male. In regard to the expectation of life relative to the size of the house it was found unexpectedly that the expectation was actually greater in a one-apartment house. The incidence of the disease, on the other hand, bore a definite relationship to the size of the house. An increase in the size of the house was associated with a decrease in the average annual incidence in adults.

The figures showed three facts: (1) A striking decline in the incidence of tuberculosis at the higher ages; (2) in young adults acute disease shows practically no decline; (3) there is a definite relationship between the size of the house and incidence of tuberculosis.

Dr. A. **SMITH** (Robroyston Hospital) read a paper on the

Treatment of Tuberculosis by Sunlight.

Artificial sunlight treatment was begun at Robroyston in January, 1925. His experience was chiefly with the carbon arc lamp. In treatment he gave a general light bath, beginning with an exposure of 20 minutes, increasing this every fourth day five minutes. Pigmentation followed—brunettes deeply and quickly, blondes with difficulty, those who freckle with difficulty, and cachectic cases scarcely at all. The carbon arc produced a brown pigment just like sunlight, the tungsten arc a reddish-brown coloration, the quartz mercury vapour a yellowish-grey. His experience showed that a good result followed in cases which became well tanned. Occasionally good results accrued even without tanning. Several striking features were noted during treatment, e.g.: (1) a rapid improvement in general health; (2) a steady gain in weight; (3) lassitude gave place to a feeling of well-being and exhilaration. An overdose, on the other hand, could depress. Excellent results were obtained in almost all cases of tuberculosis of the smaller joints and of sinuses. The hope of return of mobility and function of the joint in those cases was increased. It must be remembered that fixation could not be dispensed with during light treatment. Many notes of warning had been sounded regarding the effects of ultra-violet light in reactivating pulmonary lesions Twenty pulmonary cases had been treated by him and no catastrophes had resulted He did not see why in early pulmonary disease great benefit should not follow on light treatment

Mr W **Brownhill Smith** (Glasgow) read a paper dealing with Glasgow's solution of the smoke problem He said that it would be difficult to prove that the number of cases of illness were due to the absence or even diminution of sunlight. All, however, would admit that many cases of tuberculosis and rickets were so caused It was the duty of all medical men to preach against the evils of a smoke-laden atmosphere

An interesting demonstration of radiograms of the chest was given by Dr. **Fergus Henderson** Visits were paid to various housing schemes and sanatoriums in Glasgow, as well as to Hairmyres Training Colony at East Kilbride and the Consumption Sanatoria of Scotland, Bridge of Weir

CONGRESS OF THE ROYAL SANITARY INSTITUTE

The Jubilee Congress of the Royal Sanitary Institute was held in London from July 5th to 10th The members of the Congress attended church service at Westminster Abbey on Sunday, July 4th, when the Right Rev. the Lord Bishop of Southwark presided

At the official Congress luncheon, held on July 5th at the Hotel Victoria, Sir **Archibald Garrod** referred to the value of making the acquaintance of colleagues at conferences and the consequent increased interest taken in their work. The **Duke of Northumberland** pointed out that the Congress was even more representative of this country and the Empire than usual, and expressed the belief that much benefit would result from the focusing of public attention on the matters brought forward for discussion

The inaugural address of Mr Neville Chamberlain, President of the Congress, at the Guildhall of the City of London, was read by Dr I G **Gibbon**, Assistant Secretary to the Ministry of Health

The Minister of Health in his address compared the present state of public health with that of 50 years ago, in 1876 the general mortality rate per 1000 living was 20 9, in 1925 10 7 The infantile mortality rate in 1876 was 14 6, in 1925 75 Typhus and cholera had been practically entirely overcome, the extent of enteric fever, malaria, scarlet fever, diphtheria, and tuberculosis had been very greatly reduced. But because conditions were so much better there was danger that precautions such as vaccination may be relaxed The increase of years of working life had been a great economic gain and the lengthened life of the bread-winner had made family life more secure The abolition of disgusting smells and sights had added to the amenities of life, this in its turn reacted on health After making deductions for the advance of medical treatment and the marked rise in the standard of living, a very large part of the credit was due to the measures introduced as the result of the efforts of public health reformers There should be in the coming years great advances in dealing with those suffering from or liable to mental diseases Institutional treatment should be provided for the mentally defective Old age and widow's pensions would materially contribute to health by removing serious sources of anxiety The foundation of health as well as content lay in the economic prosperity and security of the workers of a country, the greatest health victory that could be won would be the satisfactory settlement of the present industrial dispute The founders of the Royal Sanitary Institute had helped public health by making a steady effort to raise the standard of qualification of local health officials As to the future, proper methods of sewage disposal and, in rural districts, better water-supplies were required The Smoke Abatement Bill would secure substantial improvements without any harm to industry There was room for progress in the supervision of milk and other food-supplies, but there was need for purity and plenty, not purity and scarcity Much progress had been made with housing, since 1919, over 670,000 houses had been built, over 413,000 of these with assistance from the Exchequer A further 87,000 are in course of erection and 137,000 more had been authorised Progress was being made with the clearance of slums Rural housing would be the subject of some further measures Unfortunately the money available for housing was not unlimited and the pool of available skilled labour not abundant As regards the health of individuals, one of the chief needs was to obtain more coordination of the existing services; the excellent work done by Poor-law authorities should be brought into closer relation with that of other bodies, there would still be ample need of the services of boards of guardians The Minister hoped that while retaining their voluntary character the hospitals would be able to play their part in this work.

Everyman in Preventive Medicine

On the morning of July 6th the work of the sections began Opening the discussion on Everyman in Preventive Medicine, Lord **Riddell** said that most people fail to recognise that the general public were not interested in technical subjects, even when of vital importance In attempting to popularise hygienic measures, too little attention was paid to the art of knowing how to reach the man in the street

Dr A G R **Foulerton** contributed a paper which showed the effect of bacteriological work in preventing the classical scourges of armies in the field—typhoid and typhus fevers and cholera

Dr A F **Tredgold** thought that in preventive medicine the factors of inheritance received scant attention, they had been the subject of no administrative action There existed in the community a large number of persons in whom innate tendencies to physical defect, ill-health, and disease were so marked that they must inevitably give rise to similar offspring The discussion of specific eugenic proposals could be profitably undertaken by a small competent body.

Dr H P **Newsholme** held that a healthy mind was necessary to secure a healthy body The habit of unbridled imagination which encouraged a morbid growth of the emotions should be checked The imagination must be controlled by reason, if a balanced healthy outlook was to be maintained

Modern Developments in Housing

Discussing housing, Mr F **Montague**, M P, pointed out that the wage of seven-eighths of the population is not more than £150 per annum Normal housing development was extensive rather than intensive and involved the problem of transport, the construction of the house was closely related to town-planning, its purpose being to provide a home which should be the woman's workshop, arranged to suit her convenience

Mr. E C ,P **Monson**, F R I B A, emphatically declared in favour of brick, as opposed to concrete or steel for building houses The brick was the most adaptable building unit, and was cheap and simple Concrete might be suitable for factories which present large wall spaces

Mr R **Warren**, F R I B A (Ministry of Health), said that the Building Research Board of the Department of Scientific and Industrial Research had proved most valuable He gave a short account of the new methods of house construction which had been tried

Sewage Treatment

Mr H T **Calvert**, D Sc (Ministry of Health) read a paper setting out some of the principles of the activated sludge process of sewage treatment Activated sludge was produced from sewage by a process of aeration, the exact function of the oxygen of the air being yet undetermined When mixed with fresh sewage and aerated, it coagulated certain of the solids, the colloids in suspension, and the organic matters in true solution, leaving a purified effluent In this process the activated sludge lost its virtue and had to be aerated once more Much was expected of the new bio-flocculation process at Birmingham, in which the activated sludge was allowed to do its work only in part, the partially purified effluent was then passed through percolating filters at twice or thrice its ordinary rate. By this modification an effluent of any required degree of partial purification could be obtained, and a much wider application of the activated sludge process rendered possible

At the Conference of Sanitary Inspector, Mr W G **Cooper** (Bournemouth) gave a retrospect of the work of sanitary inspectors, a plea for consolidation of the Public Health Acts was made by Mr T **Topping** (Rochester), Mr F G **McHugh** (Leicester) advocated the abolition of private slaughter-houses, and Mr R **Keeley** (Lancashire C C) read a paper on the betterment of existing housing conditions

(To be concluded)

SOUTH AFRICA

(FROM OUR OWN CORRESPONDENT)

The Medical, Dental and Pharmacy Bill

IT appears that there is little hope that either the Public Health Act Amendment Bill or the Medical, Dental and Pharmacy Bill will go further this session At the second reading of the last-named Bill in the Union House of Assembly in April the Minister of the Interior (Dr Malon) commented on the long and chequered career this Bill had had in the Union Parliament He pointed out that the measure had been scrutinised It had actually been dealt with by three select committees and referred to the various medical unions and faculties of the universities The Bill represented, therefore, the agreed opinion of all the pofessions with which it proposed to deal The measure as it stood repealed no fewer than 16 laws An Emergency Act had, however, been passed in 1917 removing certain inter-provincial difficulties in regard to practice between the various provinces, particularly so with regard to chemists and druggists The Bill made provision in respect of the sale of poisons and drugs It had been asserted that South Africa was the easiest country in which to purchase poisons and drugs

Ninety-five per cent of the Bill might be regarded, he said, as non-contentious An important part of the Bill was the provision for unification of control, so that, instead of having multifarious bodies, there would be in future one medical council for South Africa and one pharmacy board Proper representation of all the provinces was provided for Registration of practitioners under the law was provided for, so that the public would know who was and who was not registered All those now practising in the various provinces would automatically be transferred to the new Register All those who could be registered under the old laws could be registered under the new law. No change was made in regard to the registration of medical practitioners from overseas Certain safeguards were laid down, for instance, that the diplomas for medical practitioners in other countries must be of the same standard as the South African diplomas

Following the Minister's speech a somewhat heated discussion arose on the clauses relating to drugless healing The Bill provides that unqualified exponents of various cults shall not practise for gain except under medical supervision The Minister of Labour, Mr Boydell, spoke strongly against the insertion of this clause It is hardly surprising, considering the difference of opinion on certain sections of the Bill in the Cabinet itself, that the Bill is not to be put through this session

Researches on Plague in South Africa

At the annual meeting of the Rand Chamber of Mines held not long ago in Johannesburg, the President, Mr P M Anderson, called attention to the experimental investigations, bacteriological and entomological in connexion with plague as it affects South Africa which had been in progress in the South African Institute for Medical Research The researches were designed to throw light upon such questions as the comparative susceptibility to plague of various veld animals the transmission of disease by feeding on infected animals that had died, the persistence of infection in deserted burrows and many bacteriological problems The entomological work consisted mainly in the collection and identification of the parasites of field rodents with subsequent breeding, longevity feeding, and transmission experiments The last-named experiments were to discover the capability of certain fleas to convey plague from rodent to rodent

During the prosecution of these researches by Dr Harvey Pirie and Dr A Ingram it was observed that a large mortality occurred among gerbilles (among the commonest carriers of plague on the veld), which was not accounted for by plague infection, and it was eventually found to be due to a disease produced by a hitherto undiscovered bacillus Experiments are now being carried out with this organism, of which details will be published at an early date Meanwhile Dr Pirie and Dr Ingram are continuing their work in close cooperation with the Union Department of Public Health

The Retirement of Dr W Watkins-Pitchford

The impending retirement on the grounds of ill-health of Dr W Watkins-Pitchford from the directorship of the South African Institute for Medical Research will be universally regretted in this country. The connexion of Dr Watkins-Pitchford with South Africa dates from the year 1897, when the Natal Government, having decided to erect a bacteriological laboratory for the study of stock diseases, commissioned him to visit and report upon the principal laboratories of Great Britain and the continent In 1899, upon the outbreak of the Boer war, he was attached to No 7 General Hospital at Estcourt in Natal, and was entrusted with its bacteriological and pathological services In 1902 he was appointed assistant bacteriologist, and in 1907 pathologist and analyst, to the Natal Government Dr Watkins-Pitchford was the first to introduce into Natal serological tests for diseases, the bacteriological examination of water and foodstuffs, and the preparation of bacterial vaccines In 1911, following upon the union of the South African States, he was transferred to Johannesburg to undertake the duties of Government bacteriologist and pathologist for the Province of the Transvaal, and was also appointed to be analyst to the municipality of Johannesburg and honorary pathologist to the General Hospital In the same year the Witwatersrand Native Labour Association initiated a scheme for establishing an institution to be devoted to the purpose of medical research, and a joint committee representing the Government and the Association was formed to carry out the project Dr Watkins-Pitchford was appointed first director of this institute and was associated with the architects in planning and designing the beautiful building which is now the South African Institute for Medical Research In 1916 Dr Watkins-Pitchford was made chairman of the Miners' Phthisis Medical Bureau, established to administer the medical sections of the Miners' Phthisis Act The high standing of the publications issued from the South African Institute for Medical Research is largely due to the careful editorial supervision of its director, who has spared no pains to make them into documented and clear accounts of the work that is proceeding It is not yet known who will succeed him in this and the many other posts which he has fulfilled so successfully

PARIS

(FROM OUR OWN CORRESPONDENT)

The Recent Small-pox Epidemic

THE director of the vaccination service of the Académie de Médecine, Dr Lucien Camus, has been giving some particulars of the recent outbreak of small-pox Its duration and importance were greater in the south than in Paris, in the Haute-Garonne 160 cases were notified with 45 deaths, in the Hérault 52 cases with 19 deaths, and in the department of the Seine 24 cases with 5 deaths, of which 14 cases and 2 deaths were in Paris The spread and course of the epidemic depended on how effectively the patients could be isolated, on the disinfection of contaminated things and places, and on the vaccination of individuals and groups of contacts In all the areas affected the first victims, who had spread the disease, were foreigners, and although arrangements for preventing transport of infected merchandise from abroad are nowadays satisfactory, there ought to be a rule that foreigners, with the exception of tourists and winter visitors, must be vaccinated before setting sail for France It is stated that in this epidemic, as in previous ones, members of hospital personnel often contracted and disseminated infection

An Antidote to HCN

Some interesting experiments with hydrocyanic acid have recently been made by Dr Violle, professor of hygiene in the Marseilles School of Medicine A concentration of 2 g of HCN per cubic metre of air will kill an animal in a few minutes, but Dr Violle has discovered that animals which have previously had a dose of glucose (by injection or by mouth) can breathe this toxic atmosphere for more than an hour without ill-effects The glucose apparently enables them to neutralise hydrocyanic acid, and the tissues are able to deal with relatively enormous quantities These remarkable findings, if confirmed, should have a practical application, since glucose might be used as a prophylactic by those whose work brings them into contact with the gas itself—e g, in cleaning ships of rats—and those who have to handle cyanide compounds

Centenary of Laënnec

Next December Paris will commemorate the hundredth anniversary of the death of Laennec A large number of foreign savants have promised to support the committee which is arranging the centenary celebrations, and it is felt that a tribute paid to the memory of Laennec can hardly leave any doctor indifferent The treasurer of the committee is M Masson, 120, Boulevard Saint Germain, Paris, VIe The full programme, which will soon be published, includes a celebration at Ploaré, Finistère, Brittany, on August 12th Laennec died at the manor of Kerlouarnec, Ploaré, on August 13th 1826

Medical Fees

Free medical service in the Paris suburbs has recently been included under the administration of the Prefect of the Seine The medical organisations (syndicats) are protesting against the unduly small fees allowed by the State for the treatment and care of indigent patients The only fees demanded by the physicians are Fr 10 for visiting a house and Fr 8 for an interview at the doctor's consulting-room These sums are certainly not remunerative, especially in view of the rising cost of living The physicians are disposed to endure present bad conditions as far as possible, and will not cease to aid the poor, but they insist on fairer treatment than that now accorded them

Modifying the Action of Insulin

Bertrand and Mâcheboeuf have just presented to the Académie des Sciences the results of experiments, made in dogs and rabbits, tending to show that certain substances are capable of modifying and reinforcing the action of insulin The addition of small quantities of nickel or cobalt seems clearly to enhance the therapeutic effects of insulin, and these results may be important in clinical practice

The Antiluetic Campaign

A conference was held at Paris on June 18th, when Prof Bayet, of Brussels, was the principal speaker He states that syphilis, after material diminution, has become almost as prevalent in France as it was before the war The increase is ascribed to wholesale immigration, to neglect of the arsenical preparations in favour of bismuth and new compounds, and to the absence of a concerted movement against syphilis In Belgium, the urging of vigorous treatment, provision of free medical care, and extremely active propaganda, have together reduced the frequency of syphilis by four-fifths, as compared with 1920–21 Prof Bayet considers that the International Union against the Venereal Peril, formed at Paris three years ago is the most effective organisation for combating venereal disease, especially because more than 40 nations are represented in it

Illegal Practice of Medicine by Foreigners

According to information supplied by the French Ministry of Justice, some 20 Russian physicians have been prosecuted for practising medicine illegally in Paris Certain privileges have been extended to Russian physicians who served with the Allies during the war but no alterations have been made or are contemplated in the law of 1892 regulating the practice of medicine in France

The last French congress on balneology and hydrology adopted a resolution looking to the creation of a new chair in therapeutic hydrology at the Faculté de Médecine of Paris All the organisations interested in climatology, hydrology, and kindred subjects have given support to the movement, and a Bill is being prepared with clauses providing for due allotment of the Government funds toward maintenance of a new department and chair

A conference on medicine, surgery, and public health, called Journées Médicales de Paris, will be held at the Grand Palais, Paris, from July 15th to 19th inclusive The programme is very complete and many eminent men will take part Further information may be had from the Secretary-General, Dr Dujarric de la Rivière, 18, rue de Verneuil, Paris, VIIe

The subjects arranged for special discussion at the neurological meeting of 1927 are (1) normal and pathological sleep, and (2) methods of exploring the vestibular apparatus The rapporteurs for the first subject are Lhermitte and Tournay, for the second Magnus (of Utrecht) and Hautant

Dr E Sorrel, surgeon in chief of the Hôpital Maritime de Berck Plage will hold a course on Surgical Tuberculosis at the hospital from July 19th to 31st Particulars may be had from Dr Delahaye, Hôpital Maritime de Berck Plage, Pas de Calais

---

SKILLED TREATMENT FOR PATIENTS OF MODERATE MEANS —The annual report has just been issued of St Chad's Hospital, Edgbaston, a self-supporting institution which treats patients who pay an inclusive fee not exceeding 12 guineas a week, and patients who pay the medical attendant independently of the nursing charge The report states that 88 per cent of the inmates pay inclusive fees, which are less than half the usual cost of the treatment they receive Twelve years' practical experience has taught the committee that the problem to be found is not to be solved by the provision of cheap nursing-home accommodation, and they feel that the hospital could be made of real value to many who cannot at present avail themselves of its help if some simple system of insurance could be provided They think that a premium of 20*s* to 25*s* per individual would be adequate, and they are prepared to accept and treat any patients insured by an outside body in approved lives at a fixed scale, irrespective of the kind of treatment required

Correspondence.

SURGICAL TREATMENT OF GASTRIC AND DUODENAL ULCERS

To the Editor of THE LANCET

SIR,—The line of treatment to be adopted with perforated gastric and duodenal ulcers has been a frequent subject of discussion, and the conclusion has generally been arrived at that for a complete cure something further than simple suture will be required. Some surgeons have held views similar to those of Mr. Hughes and Mr. Ley, and have advised against the use of gastro-enterostomy. In the present discussion this line of treatment has been supported to the exclusion of all others, and the statement has been so dogmatically made that other methods are incorrect as to lead to the belief that no other views are held. This is far from being the case.

Whether gastro-enterostomy be performed at the time of the perforation will depend upon the patient's condition and the surgeons ability to carry out the anastomosis rapidly and with a minimum amount of shock, and there will often be considerable justification for the belief that it is better left. That simple suture is sufficient to bring about a permanent cure is, however, a view with which many will disagree. If it is a fact, then the whole surgery of gastric and duodenal ulceration must be incorrect, for should it alone be necessary to convert a perforated into an unperforated ulcer then chronic ulcers as a class should not require any surgical treatment. My own experience, and I think that of many other London surgeons, has emphatically shown that if such perforations are only closed and the cases are carefully followed up afterwards a very high percentage of them will show both clinically and on X ray investigation that the ulcer has persisted. I have had to operate upon 19 cases where a simple closure has been performed elsewhere by surgeons holding similar views to Mr. Hughes and Mr. Ley, and the patients have returned some months or years later with definite symptoms of chronic ulceration. In two cases they have sought treatment for a second perforation.

What percentage this number may represent it is impossible to say, as they have come from all parts of the country, but there is a smaller, and, from this aspect a more interesting group of cases which have been operated upon by my first assistant for perforation by simple closure, these have all been sent to my follow-up department to be watched, and there has not been a single case which has remained free from symptoms or has later failed to give X ray evidence of a chronic ulcer. The one important fact is that cases so treated should be watched over a considerable period, and I cannot but help feel suspicious of Mr. Hughes's statement that he has been kept informed about the majority of these cases. Even if the minority had persisted, they might form a considerable percentage of the total. Personally, I find that in a large number of early cases a gastro-enterostomy can be perfectly safely performed at the first stage, but should the patient be seriously ill simple closure should alone be performed, and the gastro-enterostomy left to a later date.

My one reason for entering this controversy is the fear that if the statements of Mr. Ley and Mr. Hughes gain general acceptance the after-progress of these patients will not be adequately watched, and I am confident from my own experience that a large number of them will not only be subjected to the discomforts and disabilities of recurrent ulceration, but may even have their lives endangered from the onset of later hæmorrhage or perforation.

I am, Sir, yours faithfully,

A. J. WALTON.

Devonshire street, W., July 3rd, 1926.

THE LEPROSY CAMPAIGN

To the Editor of THE LANCET

SIR,—Having just completed a tour of about 40,000 miles, on behalf of the Mission to Lepers, to investigate the present situation in the light of the new treatment, and having spent some months in the largest leper home in India, I hope that a few notes on the present situation as regards leprosy treatment may be of general interest.

I have been privileged to see a great number of homes and a variety of work in India, Burma, Siam, Borneo, and the Philippines, and have been able to view at close hand the results of a number of treatments. Much has been written during the last few years on the "specific treatment" of leprosy, but I would suggest that work as important with regard to the curing of leprosy has been done on the non-specific treatment of this disease. Leprosy is par excellence a disease of the unhealthy, and unless predisposing causes such as syphilis, hookworm, constipation, and malaria are dealt with there is very much less chance of arresting the disease.[1] In addition it is important that the leper should have abundant exercise, good food, and healthy surroundings, for unless such factors are taken into account the attempt at treatment is like trying to drive a car up a hill with the brakes on! It is now an established fact that only about 3 per cent. of lepers actually die of leprosy.

Hansen said as far back as 1895: "Most maculo-anæsthetic lepers in time become purely anæsthetic, they no longer suffer from leprosy but only from its results"[2]; this was the first and most important point that Muir re-emphasised when he called leprosy a self-healing disease.[3] It cannot be too strongly stated that many lepers cannot be helped much by the new treatment, because the anæsthesia and other signs of nerve lesions are often the result of nerve destruction, the leprosy having died out.

The treatment that is meeting with most success in India is that of hydnocarpus oil or its ester mixed with 4 per cent. creosote; the camphor mixture has been abandoned, and it has been suggested by some workers that camphor is harmful.[4] The ester is used in the following proportions: hydnocarpus ester, 50 parts; olive oil (free from fatty acids), 50 parts; double distilled creosote, 4 parts. The injections are given twice a week by the method of subcutaneous infiltration as advocated by the School of Tropical Medicine of Calcutta.[5] The dose is ½ c.cm. to commence with, gradually going up to 10 or 15 c.cm. by increments of ½ c.cm. The object is to produce well-controlled reactions. It is to be remembered that any drug which will produce reactions in leprosy tends in certain stages to produce beneficial results, and in trying new remedies this factor must not be lost sight of. For the practitioner working in the tropics, it is recommended that he should use either pure hydnocarpus oil and creosote, to the extent of 4 per cent. of creosote, or the above ester mixture. Before commencing treatment one should ask oneself the question, Is there any cause which will prevent the drug to be used from exerting its maximum effect?[5] If there is such a cause, no matter how trivial it appears to be, it should be cleared up.

Finally, with regard to prognosis, it should be borne in mind that it is not alone the question of recovery that is uppermost in the patient's mind; it is also the question of ultimate deformity. So prognoses should be based on whether the disease will be arrested with or without deformity. There is little credit in arresting leprosy if the patient ends up hopelessly mutilated If the above facts are constantly kept in mind, then I feel sure that in treating leprosy satisfactory results will accrue in the really early cases —I am, Sir, yours faithfully,

OLEOTHORAX

To the Editor of THE LANCET

SIR,—I was much interested to see from your article on the work of Kuss and Bernou on oleothorax[1] that "this new method is attracting some interest abroad" May I point out that the method is not entirely new and that it has been practised in this country for many years? In 1913 Gibbs Lloyd and Myer Coplans in Leeds made experiments to ascertain the rate of absorption of paraffin by the peritoneum in animals Before this time research had been done by an Englishman, whose name I unfortunately forget, on the absorption of paraffin by the pleura in animals In 1913, at the International Congress of Medicine in London,[2] I brought forward the subject of paraffin injections into the pleura in the treatment of pulmonary tuberculosis and gave details of two cases in which I had employed this method Saugman, who was present, encouraged the idea of this form of treatment Since then I have given injections of paraffin into the pleural cavity on more than 200 occasions in cases of pulmonary tuberculosis and also of bronchiectasis

I had two objects in mind first, to prevent adhesions between the two layers of pleura, and secondly, to compress the lung in a manner more permanent than that which is possible by means of the introduction of gas At that time I advised that an artificial pneumothorax should always be induced before the paraffin injection, and I am still of the same opinion If paraffin is injected when the pleural layers are tightly bound together by adhesions, force is required to separate them and there is then danger of shock and of embolism Whereas, if a preliminary artificial pneumothorax is performed, there is no such danger and the pressure at which the paraffin is introduced is not of major importance I have found that when the pleura is free and the lung has been compressed by a sufficient quantity of gas, adhesions are prevented by the subsequent injection of paraffin, but that when they are thick and widespread, and consequently very little gas has been introduced, these adhesions are only increased by the paraffin and there is difficulty in getting in at the next refill One may, of course, wish to increase adhesions, but I like to reserve the paraffin treatment for those cases in which gas has already been introduced and where for one reason or another it is desirable to keep the lung compressed without frequent gas refills I look upon paraffin as an alternative to the more serious procedure of thoracoplasty As to the amounts used, I give 2 drachms for an initial dose and increase the dose gradually to 6 drachms In one case of bilateral disease in a patient who was febrile and bedridden, and for whom there was no expectation of more than a few weeks of life, I introduced in all 12 ounces of paraffin together with air on the left side, where the disease was most active There was rapid and marked improvement, and for two years the patient lived in comparative comfort She then went altogether to pieces and at the post-mortem the left lung was found to be a fibrotic mass collected round the root There were several ounces of paraffin, mixed with clear serous fluid in the pleural cavity Only about one-third of the right lung was free from signs of gross disease

The question of antiseptics has been raised I find that I was using them (essential oils together with paraffin) in 1914 I was unable to see any therapeutic advantage in them I did not find that patients for whom they were used benefited more than patients who had paraffin only In one patient an acute and dangerous pleurisy followed, the disease in the lung spreading rapidly after the use of the antiseptic. This may have been merely a coincidence, but I felt the omen to be too unfavourable to allow me to continue the treatment

I am, Sir, yours faithfully,
H DE CARLE WOODCOCK
Park square, Leeds, June 30th, 1926

ENDEMIC GOITRE IN NEW ZEALAND

To the Editor of THE LANCET

SIR,—In an annotation on the above subject which appeared in THE LANCET of May 22nd (p 988) no reference is made to what is, perhaps, one of the most remarkable facts in the valuable paper with which the annotation deals[1] The fact is this, that although 96 normal children in Christchurch received "sodium iodide in graduated doses once a week for ten weeks in each of the three terms of the year" 38 of them, or 39 per cent developed thyroid enlargement during that period

In this connexion a recent statement by McClendon[2] is of interest "Thirteen towns (of Utah) with high iodine-content of the water-supply showed 39 per cent of goitre in the schools" It is true that the percentage of goitre in school-children was higher (52 per cent.) in 13 other towns of Utah where the iodine-content of the water-supply was low, as it was also higher (55 per cent) in previously normal school-children of Christchurch who received no prophylactic treatment with iodine The fact remains, however, that 39 per cent of children both in Christchurch and in Utah develop goitre despite the adequate ingestion of iodine I am, Sir, yours faithfully,

R McCARRISON

THYROID ENLARGEMENT AND THE "LACK OF IODINE" THEORY

To the Editor of THE LANCET

SIR,—Dr Fraser and Mr Tankard, in their letter of May 31st, appear to assume that the supply of iodine to the body is principally through drinking water I am not aware that any such suggestion has ever been made, although drinking water has been utilised as a medium for increasing the iodine intake of a town population

The amount of iodine in the food and drink of a locality depends, no doubt, upon the amount in the superficial layers of the soil, and has no relation whatever to the deep geological formations and the waters derived from them The intake of iodine in drinking water is probably extremely small, the body being supplied principally through vegetables, cereals, &c , and milk

McClendon, in America, has made extensive analyses, showing that the amount of iodine varies very greatly in the vegetation of different regions Similar work in this country is much wanted

I am, Sir, yours faithfully
JAMES WHEATLEY
Shrewsbury, July 1st, 1926

THE NEW HEALTH SOCIETY

To the Editor of THE LANCET

SIR,—In your editorial comment on Sir George Newman's Memorandum on the Practice of Preventive Medicine you justly term this aspect of medical practice the "fundamental principle of the future work of the medical student" Are we of the present rank and file of the profession adequately upholding this principle and putting it into practice? Or is it not the case that we are too deeply immersed in the toil and anxiety of our endeavours to promote the cure of disease to be able to find time and opportunity to deal with the individual on preventive lines? Are we trying sufficiently to educate the public to seek medical advice as a preventive rather than a curative measure? Are we instilling day by day into those who look to us for counsel the simpler precepts of healthy living? We venture to think we are not Health and the avoidance of disease depend upon our environment and our reaction thereto That the more important part of the bodily environment is determined by the individual needs no pointing out: nor the fact that unless the individual is educated in the means by which he shall adjust and control that environment he cannot be expected to succeed in attaining health

TUBERCULOSIS IN THE SHETLAND ISLANDS

To the Editor of THE LANCET

SIR—Extracted for us by Dr H Scurfield in the June *Bulletin of Hygiene* is a report by Dr J Crawford medical officer of health County of Zetland Mainland District on the tuberculosis mortality in and about Lerwick. "Tuberculosis in the Shetland Islands would seem to afford material for an extensive study of the ætiology of the disease" This is Dr H. Scurfield s remark on the report

My ignorance on the ætiology of tuberculosis in the broadest of its aspects is my excuse for the following suggestion, for I believe a similar want of data to be general amongst those who know In the report will be found that of 117 cases of tuberculosis notified during 1924 16 were of the non-pulmonary type "This is interesting because in the sanitary inspector s report we learn that the cattle slaughtered in the islands seldom show signs of tuberculosis from which we might expect non-pulmonary tuberculosis to be uncommon" (Dr Scurfield's extract) Now why should we expect any such thing? Of joint and bone lesions in 14 subjects investigated by the English Commission all save one, which was mixed infection were human tubercle; of 29 abdominal tubercle 13 were human in type of bacillus, of 9 cervical gland cases 6 were human in type Why should the fact that 16 out of 117 Shetland cases are non-pulmonary constitute the unexpected? Not certainly, because there is scanty bovine tubercle in the cattle of the islands

I would have expected less tubercle all round if here had been bovine tubercle in the islands In stating this I show, at once my ignorance and some of the lines along which investigation to the much desired enlightenment should in my humble opinion, proceed

1. The Shetland children should be subjected to some test (which I believe is not beyond our stage of knowledge to devise) and their deduced immunity (or want of it) compared with that of a comparable batch of English children who get a regular ration of tubercle in their cow's milk.

2 The cows should be tested to show how much immunity they can confer by tubercle vaccination through the milk drunk and meat eaten, and for confirmation of the sanitary inspector's report as to relative absence of bovine tubercle in the herds

3 Every human case of tubercle should be examined as to the type of bacillus

It may happen, *for anything we know to the contrary*, the parlous alleged incidence of tubercle in the Shetlands is resultant on the comparative absence of the bovine strain in the islands and consequent absence of the modicum of immunity the ingestion of constant submorbific doses of the bovine bacillus may confer in counteraction of the human type of the disease

I am Sir, yours faithfully,

W M WILLOUGHBY.

Gravesend, July 5th, 1926 M.O H, Port of London.

SOME RECENT STUDIES OF DYSENTERY: A CORRECTION.

To the Editor of THE LANCET.

SIR—In an article in THE LANCET last week (July 3rd, p 36) I am credited with having introduced a method of treating bacillary dysentery with castor oil as opposed to saline aperients This is incorrect. The castor oil treatment of bacillary dysentery was originally suggested by Dr T B Welch and Dr. C. J. Mascarenhas of the Kenya division of the East African Medical Service in a paper in the *Kenya Medical Journal* (August, 1924)

My paper was merely a statistical record of our experiences along the same lines in Uganda

I am, Sir, yours faithfully,

ARTHUR J. BOASE
East African Medical Service

New Malden, Surrey, July 2nd 1926

DONATIONS AND BEQUESTS—Mr. Edmund Turner, of Manchester left by will £3000 to his sister Janet for life, and then for Ancoats Hospital and £2000 to his sister Helen for life, with remainder to the Manchester Royal Infirmary—The late Mr William Shaw, J.P, of Martello House, Holywood Co Down left among other bequests £1000 to the Royal Victoria Hospital, Belfast, to endow a ward to be called the "Shaw Holywood" Ward.

STATE INSURANCE IN SCOTLAND—The second valuation of the Scottish approved societies shows a gross surplus of rather more than £4,000 000, of which it is expected that at least £2,500 000 will be available for distribution among 1 700,000 insured persons Every society shows a surplus and in some instances it is very large. Sir James Leishman of the Scottish Board of Health, who communicated these figures to the annual meeting of the Scottish Conference of Friendly and Approved Societies last week expressed a hope that "the medical practitioners of Scotland were not going to arouse a great distrust in their integrity, judgment, and courage, even in the face of pressure which is undoubtedly being brought to bear upon them" in the matter of certificates of fitness for work.—The Board of Health has issued a circular to insurance practitioners stating that owing to a sudden increase in the certification of claims for sickness and disablement benefit the expenditure of representative approved societies has practically doubled since the beginning of May In places the expenditure is four or five times as much as is usual at this time of year Investigation seems to indicate that a less stringent view of the statutory condition for the receipt of sickness and disablement benefit has recently been taken and the Board draws attention to the statutory condition for payment of benefit under the National Insurance Act—viz. that the insured person shall be rendered incapable of work by some specific disease or by bodily or mental disablement.

Obituary.

WILLIAM HENRY CLAYTON-GREENE, C B E, M B, CH.B CAMB, F R C S,
CHEVALIER OF THE LEGION OF HONOUR

LESS than two years after his withdrawal, when still under 50, from London surgical activities to the amenities of a much less strenuous life at Guernsey, W H Clayton-Greene died on June 29th after only two days' illness No rumour of his indisposition had reached his friends, who were shocked by the bald announcement of his sudden death when they had imagined him enjoying the quiet leisure for which he had sacrificed a brilliant career At the time of his early retirement many rumours were current as to its cause The truth was that at an age when most men are still making their reputation Clayton-Greene had long been in demand as a consultant by consultants, this type of surgical practice means an unduly large proportion of very severe cases, and involves a strain which, having accumulated a competence, he felt no longer impelled to bear It was by no means a complete withdrawal from all professional connexions, because as surgical partner in a firm of general practitioners at Guernsey he continued to do fine work It is a satisfaction to his friends that his two years there were happy ones and that he had no regrets

W H CLAYTON-GREENE

W H Clayton-Greene was born in 1874 and educated at Rossall and Corpus Christi College, Cambridge He entered at St Mary's Hospital in 1898 with the open University scholarship, and later won the Kerslake scholarship in pathology and bacteriology He qualified M R C S, L R C P in 1900, and in the following year took the M B, Ch B Camb and the F R C S He proceeded rapidly from posts as house surgeon and surgical registrar to that of surgeon to out-patients at St Mary's in 1905, when he was also appointed lecturer in anatomy to the medical school In 1911 when he was only 37, a vacancy on the full surgical staff of the hospital led to his promotion, and he held the post of surgeon to in-patients from that date until, in 1924, the unwelcome news of his retirement to the consulting staff caused real regret among colleagues and students From 1907 to 1910 Clayton-Greene was Dean of the medical school of St Mary's He was for a time surgeon to the French Hospital, to the Hampstead General Hospital, and to the Radium Institute, and during the war to the King George Hospital and to King Edward VII Hospital for Officers

Clayton-Greene served as an examiner—vigilant to maintain a high standard while not unsympathetic to those who fell below it—to many examining boards, including the University of Cambridge, the Royal College of Surgeons of England, the Conjoint Board, and the Society of Apothecaries He wrote comparatively little—to the lasting regret of his pupils, his articles in the "Index of Treatment," edited by R Hutchison and J Sherren, and the later editions of Pye's "Surgical Handicraft," which was largely rewritten by him, crystallised some of his ward teaching, but too much of it remains unrecorded His incisive delivery and a somewhat dogmatic manner made him a popular lecturer He would stride into a lecture theatre, start speaking almost before he had reached the table, and give a balanced and critical discourse on any subject in surgery There was no disease, however obscure its pathology or indefinite its course, that he could not fix as a clear picture in the minds of his hearers Students took no liberties with Clayton-Greene, few dared to be late at his classes or operations, his own punctuality was disconcerting, for he always seemed to be ready in advance of time, seated in the theatre, impatiently swinging a leg To be house surgeon to Clayton-Greene was the ambition of every St Mary's student, and no better training in efficient workmanship could be found True, he did not suffer fools gladly, and he was unsparing in his condemnation of any slackness or inefficiency which endangered the success of an operation, or militated against the comfort of a patient To those who showed ability and zeal he was always willing to give help from his wide experience, and, when this seemed to conflict with accepted teaching, to discuss the points at issue

Clayton-Greene's operative skill and precision and judgment were famous outside his own school, and drew visitors from other hospitals at home and abroad to his demonstrations He was a dramatic figure in the London surgical world, and many who had not the privilege of knowing him personally will regret his untimely death

A former colleague writes —" It is nearly 30 years since I first met Clayton-Greene, and every year of our friendship has only served to deepen and confirm my first impressions of him One could not be with him for more than a very short time without realising that one had to deal with a man of very marked individuality, and of more than average ability Others can speak of his technical skill as a surgeon, of his wonderful teaching powers, of his intimate and detailed knowledge of everything which bore on the science of his profession Only to those who lived with him was it given to know what anxious thought he gave all the time to every case under his care, and how much of his life he gave to his patients In his earlier days, when serious cases were not so numerous in his practice as they became later, there was an unfailing barometer of how any bad case was doing When he was very worried, he had a little habit of twisting his hair into points If things were going well, bedtime would come and the dark hair lay smooth on his temples, but if a case was not doing well, a fringe of twisted points stuck up along his forehead There have been great surgeons who have been able to put completely out of their minds any case except when it was immediately before them, who, when they have done all that their skill can do, can go away with an easy mind Others equally great seem to have their cases always before their eyes and always in their minds, and it was to this second class that Clayton-Greene belonged.

" In little things he could be brusque and off-hand in manner, but in the more serious matters of life he had a depth and sincerity of feeling that, once experienced, formed an unbreakable bond of friendship and love. Few men have more deeply impressed themselves on their generation and seldom has a man been so much missed as 'Clayton' has been at St Mary's."

Mr. Clayton-Greene leaves a widow and two children to whom the sympathy of all his friends and colleagues will be extended.

JOHN THOMSON, M.D., LL.D. EDIN., F.R.C.P. EDIN. & LOND.

Dr. J. Thomson died at his home in Edinburgh on July 2nd, and by his death the science and practice of pædiatrics have suffered a great loss. He was a recognised leader in that branch of medicine, and his reputation was world-wide.

John Thomson was the son of Thomas Thomson, Writer to the Signet, and was born in Edinburgh in 1856. He was sent to Edinburgh Academy and Edinburgh University, and, except for a period of study in Berlin and Vienna and a term of duty as resident medical officer at the Hospital for Sick Children, Great Ormond-street, London, his life work was done in Edinburgh. Soon after graduating, in 1881, he began to specialise in diseases of children. His work with Prof. Henoch in Berlin had confirmed a natural bent, and for over 40 years he worked at his subject with an interest that was always intense and that seemed to deepen and broaden without losing any of its heat as the years went on.

JOHN THOMSON.

In 1888 he became a Fellow of the Royal College of Physicians in Edinburgh. In the following year the New Sydenham Society published his translation of Henoch's "Diseases of Children," and a long association with the Royal Hospital for Sick Children was begun with his appointment as assistant physician. Nine years later, as the result of his teaching experience there, he published "The Clinical Study and Treatment of Sick Children," a book which established his reputation as one of the most careful clinical observers of his day. The most striking characteristic of his work was its accuracy and thoroughness: all that he wrote was based on his own experience, and he never wrote until he was sure. At a time when the growth of bacteriology and biochemistry seemed to threaten that the medical practitioner would become a mere collector of material for the laboratory specialist, he was born to demonstrate the value of clinical tradition. An excellent memory and a systematic mind enabled him to control the mass of detail which he observed, and to reduce it to order for the benefit of medical practitioners in his books and papers, and, like his friend, the late Sir James Mackenzie, he had an almost passionate desire to get at the truth.

As a teacher Thomson excelled in the out-patient room and at the bedside, where his painstaking investigation of cases and his kindly dealing with the little patients and their mothers were an example and inspiration to his students. In the lecture-room his natural diffidence made him less impressive, though the substance of his teaching was always of the highest order. At the time when he began practice in Edinburgh there were few facilities for the study of the diseases of children. The change that has taken place was to some extent inevitable, but was hastened by his influence. He started an out-patient clinic for children in connexion with the New Town Dispensary. He had much to do with the founding and working of the Edinburgh Cripple Children's Aid Society, and for over 20 years he conducted a weekly out-patient clinic for mentally defective children at the Royal Hospital for Sick Children, the only one of its kind in this country. He succeeded the late Sir William Gairdner as honorary consulting physician to the Royal Scottish National Institution for mentally defective children at Larbert. By his work on mental deficiency in children he did much to draw attention to its importance, and was largely responsible for the interest now taken in it everywhere. In late years the value of his services was generally recognised, and only a few months ago the Royal College of Physicians of London conferred on him an honorary Fellowship, at which he was greatly pleased.

The usefulness of Thomson's life, however, is only feebly reflected in a list of academic honours, and an indication of it may rather be found in his written work and in the tribute of those who learned from him. Of his many contributions to the literature of pædiatrics perhaps the most valuable were those on congenital hypertrophic pyloric stenosis and on *B. coli* infections of the urinary tract in childhood, both of which subjects he did much to bring to the notice of the profession in this country. His deep interest in the problems of mental deficiency led to the publication of a booklet entitled "Opening Doors," written to help the mothers of these unfortunate children, which is full of sympathetic insight and charm, and reflects the courage and hopefulness with which he faced the difficult cases they presented. His chief literary monument, however, is his great text-book, which, embodying as it does the observations and experience of a life time, is a mine of valuable and accurate information. Fortunately, he had been able to complete a new edition of it shortly before his death.

"When all is said," writes Dr. Robert Hutchison, "it is not as the accomplished physician and great clinical observer and teacher that his friends and pupils will always remember John Thomson, but as the humble-minded Christian gentleman that he was. Modest to a fault in his estimate of his own achievements, he was always charitable in his judgment of others. He was indeed, full of charity in the Apostle's sense; he was long suffering and kind, he envied not, vaunted not himself, was not puffed up, thought no evil. It was surely fitting that his whole life should have been devoted to the welfare of children, for he had in his own character much of the simplicity and artlessness of the child, and of such we know is the Kingdom of Heaven."

Dr. Thomson married, in 1887, Isobel, daughter of the Rev. John McPhail, of Benbecula, who survives him. He leaves three sons and two daughters.

WALTER FRANCIS RAPHAEL CASTLE, D S C, M D Camb, M R C P Lond

By the death of Dr Walter Castle, on July 1st, the medical profession loses a man who showed every promise of attaining to the front rank He died at the age of 34, and his medical career was interrupted for several years by the war, but in a comparatively short period of practice he had made himself an able dermatologist Educated at Wellington, Castle distinguished himself in all forms of sport and was head of his house He was for two years in the Eleven and in the Fifteen for three, whilst still a schoolboy he played for the Harlequins At school he was undefeated at every distance at swimming and he won the silver medal for the Public Schools heavy-weight boxing A damaged hand, however, prevented his winning further distinction in sport when he went up to Trinity College, Cambridge, where he studied for medical degrees In 1913 he took the Natural Sciences Tripos (Part I) and went on to the London Hospital, where he made many friends His success as a student seemed assured, but the natural sequence of events was changed in the following year when the war broke out, and Castle became a surgeon-probationer in the Navy In 1916 he took the L M S S A. and afterwards he was promoted surgeon serving first in the North Sea and then in the Baltic Whilst on duty with the Archangel Expedition he was awarded the Distinguished Service Cross for conspicuous gallantry After the war he settled down again to the medical career he had chosen, graduating in medicine at Cambridge in 1920 and proceeding to the M D degree in 1923 A year later he became M R C P Lond, and as dermatologist to the Queen's Hospital for Children, to the West End Hospital for Nervous Diseases, and to the Kensington, Fulham, and Chelsea General Hospital, was gaining valuable experience which had already borne fruit in a number of original articles in medical journals "His patients," writes a colleague, "will remember him as a man of surpassing kindliness, who spared himself no trouble on their behalf, quick and just in judgment, with the inestimable gift of 'being right' To his friends he will remain for all time the dearest, most open-hearted of men his kindly words, his cheery smile, his apt remark for the occasion are indelibly impressed upon our memories"

In 1921 Dr Castle married Kathleen, daughter of Mr and Mrs Charles D Seligman He leaves a son and a daughter

The late Dr Neil Maclay—The death took place suddenly on June 21st, at Bamburgh, of Dr Neil Maclay, of Newcastle-on-Tyne, at the age of 53 Dr Maclay had gone to Bamburgh for a short holiday He studied at the University of Glasgow and qualified M B and C M in 1895 For many years he had practised as a throat, nose, and ear specialist in Newcastle, where he was hon surgeon to the Throat and Ear Hospital, and aural surgeon to the Infectious Diseases Hospital He was also a trustee of the Throat and Ear Hospital, and was a past-president of the Newcastle Glasgow University Club Dr Maclay contributed numerous articles to medical journals He leaves a widow and one son

Treatment Centres for Venereal Disease—A schedule of centres approved by the Minister of Health (June, 1926) for the treatment of venereal diseases has been issued by the Ministry The days and hours of the clinics, and the facilities for irrigation treatment of gonorrhœa are detailed in the list, which supersedes that published in May, 1924

New Hospital at Barton-upon-Irwell—The Earl of Derby and Sir Thomas Robinson, M P, on July 2nd, laid the foundation-stones of the Poor-law Hospital at Davyhulme, near Manchester, to be erected by the guardians of the Barton-upon-Irwell Union, at a cost of over a quarter of a million pounds The hospital will have a maximum accommodation of 500 beds It will be known as the Park Hospital and will serve ten parishes with a population in the area of 170,000

Dentists Bill

The Bill presented in the House of Commons by Mr **Albert Alexander**, and supported by Mr **Barnes**, Mr **Robert Morrison**, Mr **Thomas Henderson**, and Mr **William Hirst**, to amend the Dentists Act, 1921, provides in the first clause that nothing in Section 5 of the Dentists Act, 1921, shall operate to prevent the carrying on of the business of dentistry by a society registered under the Industrial and Provident Societies Act, 1893, or the Friendly Societies Act, 1896 (*a*) if the business of such society, so far as it relates to the business of dentistry, is under the control and management of a superintendent who is a duly registered dentist, whose name has been forwarded to the registrar appointed under the Dentists Act, 1921, to be entered by him in a register to be kept for that purpose, (*b*) if in every premises where such business is carried on, and is not personally conducted by the superintendent, such business is bona fide conducted by a manager or assistant who is a duly registered dentist, (*c*) if all the operating staff are registered dentists

HOUSE OF COMMONS

Wednesday, June 30th

Venereal Disease in the Navy

Mr **Basil Peto** asked the First Lord of the Admiralty whether the incidence of venereal disease in the Navy had increased or diminished in the last three years, and what was the general view of the Naval Medical Service as to the value of the preventive measures that had been employed —Mr **Bridgeman** replied For the years 1922, 1923, and 1924 (the latest for which figures are available) the statistics indicate a slow but steady decrease in the incidence of venereal diseases in the Royal Navy Various preventive measures are employed—moral, physical, and medical—and it is generally considered that these have contributed collectively to the reduction

Invaliding Procedure in the Navy

Mr **Hore-Belisha** asked the First Lord of the Admiralty what procedure was followed in the case of those men invalided from His Majesty's Navy who desired to question the decision of the medical officer, which deprived them of pension rights, and whether the medical officer's report, which was the basis of the complaint, was referred to and taken as evidence of the correctness of that report —Mr **Bridgeman** replied All representations made by the rating prior to the medical survey are carefully considered by the Board of Survey These and any further representations made by him or on his behalf subsequent to the invaliding are carefully investigated by the medical authorities at the Admiralty in conjunction with the rating's medical history and with reference to conditions of his service Any medical report which may be the basis of the complaint is referred to and taken as evidence subject to further investigations or other evidence

Margarine for Butter in Poor law Institution

Mr **Lansbury** asked the Minister of Health whether he consulted his medical advisers before recommending the West Ham board of guardians to substitute margarine for butter in the dietaries prescribed for patients in the institution at Whipps Cross, and whether he would lay on the table of the House any statement he had received from such advisers wherein it was stated that the dietetic value of margarine was equal to that of butter —Sir **Kingsley Wood** replied My right hon friend has not recommended the West Ham board of guardians to make the substitution suggested The dietary of this institution is supervised by the medical officer of the institution With regard to the dietetic value of margarine I may refer the hon Member to the special report on "Diet in Relation to Normal Nutrition," issued by my department in 1921

Feeding of Miners' Children

Sir **Harry Brittain** asked the Minister of Health what attention was being given to the feeding of miners' children affected by the coal stoppage, whether reports had been received from the different sections of the country involved, and if so, what was the nature of those reports —Mr **Neville Chamberlain** replied I am keeping in constant touch through my general inspectors with the areas affected by the coal stoppage, and in reporting to me they have, at my request, paid special attention to the condition of the children A large amount of assistance is being given by the supply of meals and other food, and there is no evidence of malnutrition of children.

THURSDAY, JULY 1ST

Death in Bedford Prison

Mr PETHICK-LAWRENCE asked the Home Secretary whether he had any further statement to make with regard to his action relating to the death of Mr Reginald Russell in Bedford prison on May 23rd —Sir W JOYNSON-HICKS replied I have now given directions that the engagement of the prison medical officer, which was suspended in the course of the inquiry, shall be terminated, and that the governor, who has reached pensionable age, shall be required to retire from the service and be relieved from duty forthwith. The chief officer who has been on probation will be transferred to another prison in his former rank of principal officer, and the hospital officer will be reprimanded

New Factories Bill

Lord HENRY CAVENDISH-BENTINCK asked the Home Secretary whether he proposed under the new Factories Bill to make provision for the better regulation of offices and of underground workrooms —Sir W JOYNSON-HICKS replied · I would ask the noble lord to await the issue of the Bill which I hope to introduce this month

Qualifications of Meat Inspectors

Mr HURD asked the Minister of Health what steps were being taken to ensure that inspectors responsible for meat imports had veterinary knowledge so that they might more effectively perform their duties —Mr NEVILLE CHAMBERLAIN replied I am advised that a veterinary qualification though desirable, is not essential for the examination of imported meat from the public health point of view

Motorists and Dangerous Driving

Colonel DAY asked the Home Secretary the number of motorists in England and Wales, excluding the Metropolitan police district, who had been fined for exceeding the speed limit and/or for driving to the danger of the public, the number acquitted and the number convicted for the 12 months to the last convenient date. and the gross amount of fines and the sentences imposed —Sir W JOYNSON-HICKS replied The particulars asked for are not available In the returns furnished by the police for the purpose of compiling the criminal statistics, cases of these offences are included with other offences under a general heading for offences by motorists

Syphilis and Gonorrhœa in the Navy

Dr VERNON DAVIES asked the First Lord of the Admiralty if he would state the incidence in the Navy at home and abroad of syphilis and gonorrhœa during the last three years for which statistics were available, and in how many of these cases were preventive measures adopted —Mr DAVIDSON (Parliamentary Secretary to the Admiralty) replied · The incidence in the Navy at home and abroad of syphilis and gonorrhœa during the years 1922, 1923, and 1924 (latest figures available), is as follows —

	Ratio per 1000 sick daily		
	1922	1923	1924
Syphilis (first record)	0·70	0·96	0·53
,, (latest record)	1·16	1·02	0·84
Gonorrhœa (acute)	3·17	2·89	2·68
,, (sequelæ)	1·28	1·29	1·23

He expressed regret that no statistics were available of the number of cases in which preventive measures were adopted

MONDAY, JULY 5TH

Venereal Disease among Civil Population

Dr. VERNON DAVIES asked the Minister of Health if he had any evidence showing a lessened incidence of venereal disease amongst the civil population of this country and, if so, had he formed any opinion as to the cause of this diminution.—Mr NEVILLE CHAMBERLAIN replied As my hon friend is no doubt aware, there is no compulsory notification of cases of venereal disease in this country I am, however, advised that the returns received from the treatment centres indicate that there has been a considerable reduction during the past five years in the incidence of these diseases, and particularly of syphilis, amongst the civilian population One of the objects of the centres is to render the patients non-infective with a view to preventing the spread of venereal diseases, and I am advised that this part of the work of the centres has contributed specially to the decline in the incidence of these diseases I may refer also to the fact that the recorded mortality from syphilis, and other conditions due to syphilis, has fallen considerably since the institution of special measures for the treatment of venereal diseases.

Colonial Medical and Sanitary Services

Mr HERBERT WILLIAMS asked the Secretary of State for the Colonies whether his department was organised solely on a regional basis or whether in addition to the regional organisation, there was a staff devoted to the study of the various problems of health, agriculture, veterinary services and geological survey —Mr AMERY replied. The Colonial Office is organised primarily on a regional basis There is also a general department, which is concerned with correspondence of a general and miscellaneous character The study of the various problems mentioned in the question is promoted by reference to various committees and expert advisers such as the Colonial Advisory Medical and Sanitary Committee the Colonial Survey Committee, &c I have also recently appointed a chief medical adviser to the Colonial Office, who will advise me on medical and sanitary problems arising in connexion with the colonies and protectorates

Local Authorities and Mental Defectives

Sir COOPER RAWSON asked the Minister of Health if he had received representations from local authorities with regard to the increase of mental defectives in the country and the increasing cost of maintaining and extending institutional treatment, the effect of which was usually unsatisfactory and ineffective and whether he had considered the desirability of introducing legislation for compulsory segregation or such other methods as might be considered necessary for preventing an increase in the number of cases —Sir KINGSLEY WOOD replied The answer to the first part of the question is in the affirmative, but my right hon. friend is not aware of evidence to indicate that the incidence of mental defect is increasing Though the cost of maintaining and extending institutional treatment is heavy my right hon friend cannot accept the suggestion that it is usually either unsatisfactory or ineffective. The Mental Deficiency Act of 1913 already provides machinery by which defectives can be segregated or placed under guardianship or supervision The absence of sufficient institutional accommodation is hampering the operation of the Act, and local authorities have been urged to make further provision.

Kingston Nursing Association

Mr PENNY asked the Minister of Health if he could give the name and qualifications of the medical officer appointed by his department to inquire into the administration of the Kingston Nursing Association, and whether any previous investigations had been carried out in regard to the association.—Sir KINGSLEY WOOD replied · The officer in question is a member of the medical staff of the Ministry of Health, but my right hon. friend does not think any useful purpose would be served by giving the officer's name. For the decisions based on the investigation of this officer, however, I may refer my hon friend to the Minister's letter to the chairman of the Association (see THE LANCET, p 103) of which I am sending him a copy The maternity home belonging to the Association had been inspected on two previous occasions by medical officers of my right hon. friend's department in 1921 and 1925

New Draft Milk and Dairies Order

Brigadier-General CLIFTON BROWN asked the Minister of Health whether he was issuing a new draft Milk and Dairies Order; if so, on what date was it proposed that the Order should come into operation, and when would copies of the Order be available —Sir KINGSLEY WOOD replied: Yes, Sir. The Order has now been settled and will come into operation on Oct 1st. Copies should be available in the course of a week or so

Naval Hospital at Hong-Kong

Mr PENNY asked the First Lord of the Admiralty whether he would consider the desirability of disposing of the naval hospital at Hong-Kong, in view of the offer from the Hong-Kong Government to place a special department of the new nursing home being erected there at our disposal.—Mr DAVIDSON replied I am not aware of any offer on the lines suggested by my hon. friend.

TUESDAY, JULY 6TH.

R A M C Increases of Pay

Sir FREDRIC WISE asked the Secretary of State for War what was the extra cost for certain increases in the rates of pay, retiring gratuities, &c., of the Army Medical Corps, Dental Corps, and Veterinary Corps —Sir L. WORTHINGTON-EVANS replied The extra cost is estimated at £76 000 per annum.

Death and Sickness Rate in Gold Coast

Lieut -Commander KENWORTHY asked the Secretary of State for the Colonies the death and sickness rate amongst the natives employed in the gold-mining industry of the Gold Coast Colony during the last complete year for which statistics are available —Mr ORMSBY-GORE replied. From figures which have been supplied to me by the officer administering the government of the Gold Coast it would appear that the death-rate per 1000 amongst all labour, surface and underground, in the gold mines in the Gold Coast is approximately 8 3 No reliable figures are available as to the sicknesss rates.

Colonel **DAY** asked the Home Secretary the number of motorists in England and Wales, excluding the Metropolitan police district, who had been fined for exceeding the speed limit and/or for driving to the danger of the public, the number acquitted and the number convicted for the 12 months to the last convenient date, and the gross amount of fines and the sentences imposed —Sir W **JOYNSON-HICKS** replied The particulars asked for are not available In the returns furnished by the police for the purpose of compiling the criminal statistics, cases of these offences are included with other offences under a general heading for offences by motorists

Syphilis and Gonorrhœa in the Navy

Dr **VERNON DAVIES** asked the First Lord of the Admiralty if he would state the incidence in the Navy at home and abroad of syphilis and gonorrhœa during the last three years for which statistics were available, and in how many of these cases were preventive measures adopted —Mr **DAVIDSON** (Parliamentary Secretary to the Admiralty) replied The incidence in the Navy at home and abroad of syphilis and gonorrhœa during the years 1922, 1923, and 1924 (latest figures available), is as follows —

	Ratio per 1000 sick daily		
	1922	1923	1924
Syphilis (first record)	0 70	0 96	0 53
„ (latest record)	1 16	1 02	0 84
Gonorrhœa (acute)	3 17	2 89	2 68
„ (sequelæ)	1 28	1 29	1 23

He expressed regret that no statistics were available of the number of cases in which preventive measures were adopted

MONDAY, JULY 5TH

Venereal Disease among Civil Population

Dr **VERNON DAVIES** asked the Minister of Health if he had any evidence showing a lessened incidence of venereal disease amongst the civil population of this country, and, if so, had he formed any opinion as to the cause of this diminution —Mr **NEVILLE CHAMBERLAIN** replied As my hon. friend is no doubt aware, there is no compulsory notification of cases of venereal disease in this country I am, however, advised that the returns received from the treatment centres indicate that there has been a considerable reduction during the past five years in the incidence of these diseases, and particularly of syphilis, amongst the civilian population One of the objects of the centres is to render the patients non-infective with a view to preventing the spread of venereal diseases, and I am advised that this part of the work of the centres has contributed specially to the decline in the incidence of these diseases I may refer also to the fact that the recorded mortality from syphilis, and other conditions due to syphilis, has fallen considerably since the institution of special measures for the treatment of venereal diseases

Colonial Medical and Sanitary Services

Mr **HERBERT WILLIAMS** asked the Secretary of State for the Colonies whether his department was organised solely on a regional basis or whether, in addition to the regional organisation, there was a staff devoted to the study of the various problems of health, agriculture, veterinary services, and geological survey —Mr **AMERY** replied The Colonial Office is organised primarily on a regional basis There is also a general department, which is concerned with correspondence of a general and miscellaneous character The study of the various problems mentioned in the question is promoted by reference to various committees, and expert advisers such as the Colonial Advisory Medical and Sanitary Committee, the Colonial Survey Committee, &c I have also recently appointed a chief medical adviser to the Colonial Office, who will advise me on medical and sanitary problems arising in connexion with the colonies and protectorates

Local Authorities and Mental Defectives

Sir **COOPER RAWSON** asked the Minister of Health if he had received representations from local authorities with regard to the increase of mental defectives in the country and the increasing cost of maintaining and extending institutional treatment, the effect of which was usually unsatisfactory and ineffective and whether he had considered the desirability of introducing legislation for compulsory segregation or such other methods as might be considered necessary for preventing an increase in the number of cases —Sir **KINGSLEY WOOD** replied The answer to the first part of the question is in the affirmative, but my right hon friend is not aware of evidence to indicate that the incidence of mental defect is increasing Though the cost of maintaining and extending institutional treatment is heavy my right hon friend cannot accept the suggestion that it is usually either unsatisfactory or ineffective The Mental Deficiency Act of 1913 already provides machinery by which defectives can be segregated or placed under guardianship or supervision The absence of sufficient institutional accommodation is hampering the operation of the Act, and local authorities have been urged to make further provision

Kingston Nursing Association

Mr **PENNY** asked the Minister of Health if he could give the name and qualifications of the medical officer appointed by his department to inquire into the administration of the Kingston Nursing Association, and whether any previous investigations had been carried out in regard to the association —Sir **KINGSLEY WOOD** replied The officer in question is a member of the medical staff of the Ministry of Health, but my right hon friend does not think any useful purpose would be served by giving the officer's name For the decisions based on the investigation of this officer, however, I may refer my hon friend to the Minister's letter to the chairman of the Association (see THE LANCET, p 103) of which I am sending him a copy The maternity home belonging to the Association had been inspected on two previous occasions by medical officers of my right hon. friend's department in 1921 and 1925

New Draft Milk and Dairies Order

Brigadier-General **CLIFTON BROWN** asked the Minister of Health whether he was issuing a new draft Milk and Dairies Order, if so, on what date was it proposed that the Order should come into operation, and when would copies of the Order be available —Sir **KINGSLEY WOOD** replied Yes, Sir The Order has now been settled and will come into operation on Oct 1st Copies should be available in the course of a week or so

Naval Hospital at Hong-Kong

Mr **PENNY** asked the First Lord of the Admiralty whether he would consider the desirability of disposing of the naval hospital at Hong-Kong, in view of the offer from the Hong-Kong Government to place a special department of the new nursing home being erected there at our disposal —Mr **DAVIDSON** replied I am not aware of any offer on the lines suggested by my hon friend

TUESDAY, JULY 6TH

R A M C Increases of Pay

Sir **FREDRIC WISE** asked the Secretary of State for War what was the extra cost for certain increases in the rates of pay, retiring gratuities, &c, of the Army Medical Corps, Dental Corps, and Veterinary Corps —Sir L. **WORTHINGTON-EVANS** replied The extra cost is estimated at £76,000 per annum

Death and Sickness Rate in Gold Coast

Lieut -Commander **KENWORTHY** asked the Secretary of State for the Colonies the death and sickness rate amongst the natives employed in the gold-mining industry of the Gold Coast Colony during the last complete year for which statistics are available —Mr **ORMSBY-GORE** replied From figures which have been supplied to me by the officer administering the government of the Gold Coast, it would appear that the death-rate per 1000 amongst all labour, surface and underground, in the gold mines in the Gold Coast is approximately 8 3 No reliable figures are available as to the sicknesss rates

WALTER FRANCIS RAPHAEL CASTLE, D S C, M.D CAMB, M R C P LOND

BY the death of Dr Walter Castle, on July 1st, the medical profession loses a man who showed every promise of attaining to the front rank He died at the age of 34, and his medical career was interrupted for several years by the war, but in a comparatively short period of practice he had made himself an able dermatologist Educated at Wellington, Castle distinguished himself in all forms of sport and was head of his house He was for two years in the Eleven and in the Fifteen for three, whilst still a schoolboy he played for the Harlequins At school he was undefeated at every distance at swimming, and he won the silver medal for the Public Schools heavy-weight boxing A damaged hand, however, prevented his winning further distinction in sport when he went up to Trinity College, Cambridge, where he studied for medical degrees In 1913 he took the Natural Sciences Tripos (Part I) and went on to the London Hospital, where he made many friends His success as a student seemed assured, but the natural sequence of events was changed in the following year when the war broke out, and Castle became a surgeon-probationer in the Navy In 1916 he took the L M S S A and afterwards he was promoted surgeon serving first in the North Sea and then in the Baltic Whilst on duty with the Archangel Expedition he was awarded the Distinguished Service Cross for conspicuous gallantry After the war he settled down again to the medical career he had chosen, graduating in medicine at Cambridge in 1920 and proceeding to the M D degree in 1923 A year later he became M R C P Lond, and as dermatologist to the Queen's Hospital for Children, to the West End Hospital for Nervous Diseases, and to the Kensington, Fulham, and Chelsea General Hospital was gaining valuable experience which had already borne fruit in a number of original articles in medical journals "His patients," writes a colleague, "will remember him as a man of surpassing kindliness, who spared himself no trouble on their behalf, quick and just in judgment, with the inestimable gift of 'being right' To his friends he will remain for all time the dearest, most open-hearted of men his kindly words, his cheery smile, his apt remark for the occasion are indelibly impressed upon our memories"

In 1921 Dr Castle married Kathleen, daughter of Mr and Mrs Charles D Seligman. He leaves a son and a daughter

---

THE LATE DR NEIL MACLAY—The death took place suddenly on June 21st, at Bamburgh, of Dr Neil Maclay, of Newcastle-on-Tyne, at the age of 53 Dr Maclay had gone to Bamburgh for a short holiday He studied at the University of Glasgow and qualified M B and C M in 1895 For many years he had practised as a throat, nose, and ear specialist in Newcastle, where he was hon surgeon to the Throat and Ear Hospital, and aural surgeon to the Infectious Diseases Hospital He was also a trustee of the Throat and Ear Hospital, and was a past-president of the Newcastle Glasgow University Club Dr Maclay contributed numerous articles to medical journals He leaves a widow and one son

---

TREATMENT CENTRES FOR VENEREAL DISEASE—A schedule of centres approved by the Minister of Health (June, 1926) for the treatment of venereal diseases has been issued by the Ministry The days and hours of the clinics, and the facilities for irrigation treatment of gonorrhœa are detailed in the list, which supersedes that published in May, 1924

NEW HOSPITAL AT BARTON-UPON-IRWELL—The Earl of Derby and Sir Thomas Robinson, M P, on July 2nd, laid the foundation-stones of the Poor-law Hospital at Davyhulme, near Manchester, to be erected by the guardians of the Barton-upon-Irwell Union, at a cost of over a quarter of a million pounds The hospital will have a maximum accommodation of 500 beds It will be known as the Park Hospital and will serve ten parishes with a population in the area of 170,000

NOTES ON CURRENT TOPICS

Dentists Bill.

THE Bill presented in the House of Commons by Mr ALBERT ALEXANDER, and supported by Mr BARNES, Mr ROBERT MORRISON, Mr THOMAS HENDERSON, and Mr WILLIAM HIRST, to amend the Dentists Act, 1921, provides in the first clause that nothing in Section 5 of the Dentists Act, 1921, shall operate to prevent the carrying on of the business of dentistry by a society registered under the Industrial and Provident Societies Act, 1893, or the Friendly Societies Act, 1896 (*a*) if the business of such society, so far as it relates to the business of dentistry, is under the control and management of a superintendent who is a duly registered dentist, whose name has been forwarded to the registrar appointed under the Dentists Act, 1921, to be entered by him in a register to be kept for that purpose, (*b*) if in every premises where such business is carried on, and is not personally conducted by the superintendent such business is bona fide conducted by a manager or assistant who is a duly registered dentist, (*c*) if all the operating staff are registered dentists

HOUSE OF COMMONS

WEDNESDAY, JUNE 30TH

Venereal Disease in the Navy

Mr BASIL PETO asked the First Lord of the Admiralty whether the incidence of venereal disease in the Navy had increased or diminished in the last three years, and what was the general view of the Naval Medical Service as to the value of the preventive measures that had been employed.—Mr BRIDGEMAN replied For the years 1922, 1923, and 1924 (the latest for which figures are available) the statistics indicate a slow but steady decrease in the incidence of venereal diseases in the Royal Navy Various preventive measures are employed—moral, physical, and medical—and it is generally considered that these have contributed collectively to the reduction

Invaliding Procedure in the Navy

Mr HORE-BELISHA asked the First Lord of the Admiralty what procedure was followed in the case of those men invalided from His Majesty's Navy who desired to question the decision of the medical officer, which deprived them of pension rights, and whether the medical officer's report, which was the basis of the complaint, was referred to and taken as evidence of the correctness of that report—Mr BRIDGEMAN replied All representations made by the rating prior to the medical survey are carefully considered by the Board of Survey These and any further representations made by him or on his behalf subsequent to the invaliding are carefully investigated by the medical authorities at the Admiralty in conjunction with the rating's medical history and with reference to conditions of his service Any medical report which may be the basis of the complaint is referred to and taken as evidence subject to further investigations or other evidence

Margarine for Butter in Poor-law Institution

Mr LANSBURY asked the Minister of Health whether he consulted his medical advisers before recommending the West Ham board of guardians to substitute margarine for butter in the dietaries prescribed for patients in the institution at Whipps Cross, and whether he would lay on the table of the House any statement he had received from such advisers wherein it was stated that the dietetic value of margarine was equal to that of butter—Sir KINGSLEY WOOD replied My right hon friend has not recommended the West Ham board of guardians to make the substitution suggested. The dietary of this institution is supervised by the medical officer of the institution With regard to the dietetic value of margarine I may refer the hon Member to the special report on "Diet in Relation to Normal Nutrition," issued by my department in 1921

Feeding of Miners' Children

Sir HARRY BRITTAIN asked the Minister of Health what attention was being given to the feeding of miners' children affected by the coal stoppage, whether reports had been received from the different sections of the country involved, and if so, what was the nature of those reports—Mr NEVILLE CHAMBERLAIN replied I am keeping in constant touch through my general inspectors with the areas affected by the coal stoppage, and in reporting to me they have, at my request, paid special attention to the condition of the children A large amount of assistance is being given by the supply of meals and other food, and there is no evidence of malnutrition of children.

THURSDAY, JULY 1ST

Death in Bedford Prison

Mr PETHICK-LAWRENCE asked the Home Secretary whether he had any further statement to make with regard to his action relating to the death of Mr Reginald Russell in Bedford prison on May 23rd —Sir W JOYNSON-HICKS replied I have now given directions that the engagement of the prison medical officer, which was suspended in the course of the inquiry, shall be terminated, and that the governor, who has reached pensionable age, shall be required to retire from the service and be relieved from duty forthwith The chief officer who has been on probation will be transferred to another prison in his former rank of principal officer, and the hospital officer will be reprimanded

New Factories Bill

Lord HENRY CAVENDISH-BENTINCK asked the Home Secretary whether he proposed under the new Factories Bill to make provision for the better regulation of offices and of underground workrooms —Sir W JOYNSON-HICKS replied I would ask the noble lord to await the issue of the Bill which I hope to introduce this month

Qualifications of Meat Inspectors

Mr HURD asked the Minister of Health what steps were being taken to ensure that inspectors responsible for meat imports had veterinary knowledge so that they might more effectively perform their duties —Mr NEVILLE CHAMBERLAIN replied I am advised that a veterinary qualification, though desirable, is not essential for the examination of imported meat from the public health point of view

Motorists and Dangerous Driving

Colonel DAY asked the Home Secretary the number of motorists in England and Wales, excluding the Metropolitan police district, who had been fined for exceeding the speed limit and/or for driving to the danger of the public, the number acquitted and the number convicted for the 12 months to the last convenient date, and the gross amount of fines and the sentences imposed —Sir W JOYNSON-HICKS replied The particulars asked for are not available In the returns furnished by the police for the purpose of compiling the criminal statistics, cases of these offences are included with other offences under a general heading for offences by motorists

Syphilis and Gonorrhœa in the Navy

Dr VERNON DAVIES asked the First Lord of the Admiralty if he would state the incidence in the Navy at home and abroad of syphilis and gonorrhœa during the last three years for which statistics were available, and in how many of these cases were preventive measures adopted —Mr DAVIDSON (Parliamentary Secretary to the Admiralty) replied The incidence in the Navy at home and abroad of syphilis and gonorrhœa during the years 1922, 1923, and 1924 (latest figures available), is as follows —

	Ratio per 1000 sick daily		
	1922	1923	1924
Syphilis (first record)	0 70	0 96	0 53
„ (latest record)	1 16	1 02	0 84
Gonorrhœa (acute)	3 17	2 89	2 68
„ (sequelæ)	1 28	1 29	1 23

He expressed regret that no statistics were available of the number of cases in which preventive measures were adopted

Amongst well-known medical men from many countries who are to give lectures will be Prof George Barger, of Edinburgh, who will speak on the Chemistry of the Hormones Foreign doctors attending the course will receive special facilities from the Czecho Slovakian government and from the municipality of Karlsbad Further information may be had from the secretary of the course, Dr Edgar Ganz, Karlsbad

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION —The presidential address of this Association will be delivered on Tuesday July 13th, at 3 P M., by Lieut -Colonel J R Lord, C B E, at the house of the B M A., Tavistock square, W C, the subject being the Clinical Study of Mental Disorders On Thursday, July 15th, at 3 P.M., the Maudsley lecture will be delivered by Prof G M Robertson, President of the Royal College of Physicians of Edinburgh, who in the course of his address will survey the problems presented in the endeavour to prevent insanity On the same evening the annual dinner of the Association will take place at 7 15 P M in the Edward VII. Rooms, Victoria Hotel, London, W C

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —Mr Rocyn-Jones will give a clinical demonstration in surgery at the Royal National Orthopædic Hospital, on Monday, July 12th, at 2 P M., and Mr Griffith will give a demonstration in ophthalmology at the Royal Eye Hospital on Wednesday, July 14th, at 3 P M. These will be open to all members of the medical profession without fee A post-graduate vacation course will be held from July 19th to 31st at the North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N 15), the course is especially intended for medical men and women in active practice It will consist of morning demonstrations, each day from 10 30 A M to 12 45 P M., on modern clinical and laboratory methods included under the name of side-room work, demonstrations of groups of selected cases from 2 to 2 45 P M each day and from 2 45 P M. onwards of general hospital work, in-patient and out patient clinics, operation, and demonstration in the special department At 4 30 P M daily there will be a clinical lecture, the opening lecture of the first week will be given by Dr T W Eden on Antenatal Care as it Affects the Child in utero, and that of the second week by Lieut-Colonel L W Harrison on the Diagnosis and Treatment of Syphilis, will be illustrated by a cinematograph demonstration Visits will be made to a fever hospital and a mental hospital on Saturday mornings The names of those wishing to attend should be sent in, if possible, by July 16th There will be a late afternoon course (from 5 P M) at the West End Hospital for Nervous Diseases from July 19th to August 12th. Lectures and demonstrations on selected cases will be given in the out-patient department, 73, Welbeck-street, London W, and there will be a pathological demonstration at the in-patient department, Gloucester-gate, N W, on Monday, July 19th Practical courses in obstetrics and child welfare are to be held throughout the year at the City of London Maternity Hospital The courses will last one week and the fee is £2 2*s* Practical courses in anæsthetics can be arranged at any time From August 9th to 14th there will be an intensive course at the Brompton Hospital, from August 16th to 28th an all-day course in diseases of children at the Queen's Hospital, and from August 23rd to Sept 7th an all day course in medicine, surgery, and the specialities at the Queen Mary's Hospital Copies of all syllabuses, of the general course programme, and of the *Post-Graduate Medical Journal*, may be had on application to the Secretary of the Fellowship at 1, Wimpole street, London,

Royal Hospital Morningside—A luncheon will e given by the Chairman and Managers of the institution t Vogrie on Thursday, July 22nd, in celebration of the nauguration of the new nursing home

St Bartholomew's Hospital War Memorial—This memorial which takes the form of an archway under he Great Hall connecting the square and the school, was nveiled by the Prince of Wales on July 8th

The late Lieut -Colonel Lionel Pisani F R C S I M S (Retd)—After a short illness Colonel Pisani died on June 22nd in his sixty-fourth year He was a student at the Charing Cross Hospital, qualified in 1886 and a month later passed into the I M S being placed first on the list of candidates On arriving in India he was appointed to the guides and saw service on the frontier From 1890 to 1909 he was in charge of civil districts in the United Provinces He planned, equipped, and had charge of the Government Hospital at Moradabad where, in addition to general surgical operations, about 200 cataract extractions were performed annually Leaving India for family reasons in 1909, he determined to devote himself to ophthalmology, and with this aim and in spite of his large experience in operative work he entered Moorfields Hospital as a junior assistant, and in due course became chief clinical assistant In 1911 he was appointed ophthalmic surgeon to the Metropolitan Hospital, and later consulting ophthalmologist to the Metropolitan Asylums Board, in this capacity visiting the asylums at Watford and the schools at Banstead Pisani was a man of untiring energy apart from vacation absences he never missed a day's attendance at hospital, and he visited the Watford Asylum the day before he took to his bed

Prize-giving at the London Hospital—On June 28th Mr Neville Chamberlain, Minister of Health presented prizes to the students of the London Hospital Medical College Prof William Wright Dean of the College, said that during the year 1925–26, 582 students had been in attendance, 103 of whom had taken medical or dental degrees or diplomas By resignation the hospital had lost the services of Dr Russell Andrews, Mr James Sherren, and Dr E W Clapham, who in their several ways were representative of the London Hospital, and imbued with its finest traditions Those who had been elected to the staff during the year were Mr W Morris and Mr Geoffrey Carte as assistant aural surgeons Dr A Maitland-Jones as director of the new department of the diseases of children, Dr W J O'Donovan as assistant physician in the dermatological department, Mr Victor Lack as assistant physician in the obstetric department, Mr A C Perry and Mr H W B Cairns as assistant surgeons, Mr A G Allen as dental surgeon, and Mr Stuart Thompson as assistant anæsthetist After mention of the various endowments received by the hospital during a memorable year, Prof Wright referred to the appointment of Dr S P Bedson, Dr Howard Florey, and Dr L Hewitt as workers under the Freedom Research Fund, and concluded by reminding his audience of the quite extraordinary opportunities offered by the London Hospital to students of medicine now that 100 junior appointments were open to recently qualified men and about £100,000 had been made available for research The facilities for giving a broad, thorough, and modern education, both theoretical and practical, to undergraduates and postgraduates alike were, he considered, greater than those offered by any similar institution in the country Mr Neville Chamberlain having presented the prizes referred to the possible careers open to the student, emphasising the claims of preventive medicine From the point of view of a Minister of Health, he said, it was almost impossible to lay too much stress upon the need for continual research The organisation of medicine in this country was, unfortunately, far from perfect, but it was the task of the Minister to try to adjust defects in the machinery In this task he asked the coöperation of his hearers Lord Knutsford in moving a vote of thanks to Mr Chamberlain, said that the duty of the hospital did not end when it simply cured the sick who came for help , part of its duty was to discover the causes of the sickness Unfortunately, at the London Hospital there was a list of over 1100 people waiting for admission, and until recently the lack of funds had prevented adequate endowment of research Lord Dawson of Penn seconding the vote of thanks, said that the changes coming over the practice of medicine were likely to be wide and deep The centre of gravity was drifting away from disease and towards health The doctor of the future would study early disturbance of function, and it seemed inevitable that there would be a large development in what might be called industrial medicine People would be studied chiefly in relation to their work and its environment, with the result that practice would diminish in the surgery and the home This would involve an increase of clinics and hospitals and the primary hospitals of the future would play an important part in every local community, where they would be closely associated with the work of the general practitioner

Biochemical Society—At the meeting of this society to be held in the Department of Biochemistry at Oxford at 2 30 P M to-day, Saturday July 10th there will be biochemical demonstrations and a number of original communications will be read.

Andover War Memorial Hospital—On June 30th Field-Marshal Viscount Allenby opened the hospital erected as part of the war memorial at Andover Hampshire The building supersedes the old cottage hospital and has been put up at a cost of £16 000 There is accommodation for 24 patients and the capacity can easily be increased later, and there is also a well-equipped operating theatre Dr E A Farr chairman of the hospital building committee was able to announce that the hospital opened practically free of debt. An informal visit to the hospital was recently paid by the Prince of Wales

The King at Papworth—The King last week visited the Tuberculosis Colony at Papworth near Cambridge, and before leaving, His Majesty told Dr P C Varrier-Jones, the medical director that the colony was "the most perfect scheme that he had ever seen" A tour of the industrial side of the colony to occupy an hour had been mapped out but the King was so much interested in all that he saw that he spent two hours in the works. He bought a large leather cabin trunk and was presented with a pigskin suit-case by the workers

Larger Northern Hospitals—Lord Darlington has laid the foundation-stone of a new War Memorial Hospital at Darlington The total cost will be £185,000, of which about one-third has yet to be raised—Lady Sutherland has laid the foundation-stone of a new wing of the Beckett Hospital at Barnsley, which is estimated to cost £25 000 of which only one-half is yet available. The hospital has a waiting-list of 200, and the present accommodation is equivalent to no more than half a bed per 1000 of the population, which is growing rapidly.—The newly-completed wing of the Lloyd Hospital at Bridlington has been opened by Lady Cunliffe-Lister, the wife of the President of the Board of Trade The hospital was established on a small scale in 1868 by Miss Lloyd, Sir P Cunliffe-Lister's great-aunt The new wing contains 20 beds in four wards

Kingston District Nursing Association—The Minister of Health has addressed a letter to the Chairman of the Kingston District Nursing Association in regard to the cases of septic infection which have occurred recently among patients attended by nurses on the staff of this Association, and have been the subject of questions in Parliament He states that the facts elicited by the inquiry indicate that there was grave laxity on the part of the superintendent in the administration of the maternity home and of the extern midwifery practice She apparently failed to realise the risk of permitting the same nurse to have access to infected and non-infected patients and she even allowed a nurse who was herself suffering from septic infection to remain on duty in spite of her manifest unfitness to continue to attend maternity patients He adds that there can be little doubt that this nurse acted as a carrier of virulent infection from one patient to another and, although the ultimate responsibility for permitting this must devolve upon the superintendent the nurse herself cannot be exonerated from blame It is only fair to the superintendent to add, says the letter that she suspected infection in a patient attended by this nurse although the medical practitioner in charge of the case appears to have failed to diagnose the condition or to recognise the patient as a source of infection The Minister considers that no useful purpose would be served by reviewing in detail the incidents of the outbreak but he is compelled to recognise that the negligence of the staff has contributed in large measure to the calamities which were the occasion of this inquiry Moreover he cannot escape the impression that the medical care of more than one of the cases does not seem, as far as the evidence shows to have been in accordance with the principles of sound midwifery practice It is understood that the maternity home has been closed temporarily, and that the district midwifery practice is in abeyance for the time being The Minister considers that the committee would be well advised, when maternity work is resumed, not only to replace the superintendent and the nurse directly concerned with the recent infected cases but in view of the laxity in administration revealed by the inquiry to appoint an entirely new midwifery staff He trusts that the committee will not be unduly discouraged by what has happened, and that the valuable public service rendered by the Association will not be allowed to lapse He suggests however that it might be advisable for the committee to consider affiliation of their Association with the Surrey County Nursing Association

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole street, W
TUESDAY, WEDNESDAY and THURSDAY July 13th–15th—ANÆSTHETICS Visit of American and Canadian Anæsthetists Tuesday, 10 A M Papers by Prof J S Haldane, Mr F P Dunhill, and Dr J Blomfield Thursday 10 A M American Session DINNER On Wednesday a Complimentary Dinner will be given by the Section of Anæsthetics to the visitors and their wives Tickets, inclusive of wine 25s each

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION, 1, Wimpole street, London, W
MONDAY, July 12th, to SATURDAY, July 17th—Special demonstration in clinical surgery at the Royal National Orthopædic Hospital, 234, Great Portland street, W on Monday at 2 P M, by Mr Rocyn Jones Special demonstration in clinical ophthalmology at the Royal Eye Hospital Southwark on Wednesday, at 3 P M by Mr Griffith—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars, S E Afternoon course in Dermatology consisting of instruction in the Out-Patient Department (selected cases by Mr Haldin Davis)—ROYAL EYE HOSPITAL, Southwark S E A series of demonstrations on the diagnosis and treatment of Diseases of the Eye will be given by members of the staff from Monday to Friday, inclusive, at 3 P M Further information from the Secretary of the Fellowship of Medicine

NORTH-EAST LONDON POST GRADUATE COLLEGE Prince of Wales's General Hospital, Tottenham, N

Notes, Comments, and Abstracts.

PUBLIC HEALTH IN CHINA AND THE BOXER INDEMNITY

BY SURGEON-GENERAL S. H. CHUAN,
MINISTRY OF WAR, PEKING

As gestures of goodwill, different nations in the past few years have either remitted to China, or decided to use for China's benefit, the unpaid portions of their Boxer Indemnity Funds. Such funds have been assigned to various worthy causes. The United States of America to education and culture; France to the stabilisation of finances; Holland to Yellow River conservancy; and Japan to library and research laboratory. It is needless to say that China deeply appreciates such generous deeds, and that funds so used will not only benefit China and the nations concerned, but will also result in advancing further the cause of international peace and brotherhood.

Remission or Allocation of Indemnity

It augurs well for the future international relations in the Far East to know that Great Britain has recently decided also to take similar action regarding the balance of her Boxer Indemnity. It is significant to note that so much importance is placed on the best use of the funds that a commission, headed by such a distinguished statesman as Viscount Willingdon, and assisted by British and Chinese possessing the confidence of this country, has been studying the local needs and conditions, gathering at first hand all necessary information which will enable the Statutory Committee to render its final decision on "the best use of the indemnity funds for the mutual interests" of Great Britain and China.

During the past year more than a few proposals have been made either to the British Government or to the Willingdon Delegation, concerning the allocation of the British Boxer Indemnity. There is no doubt that all these proposals have been made by parties bearing in mind only the needs and welfare of China, and that they are all worthy of careful and favourable consideration. It is, therefore, with due respect for, and full appreciation of the value of the other proposals that I wish to write a few lines in favour of the proposal suggesting the allocation of at least a part of the British Boxer Indemnity Funds to the promotion of public health in China.

It seems to me that in deciding on the best use of the said funds, these factors should be of primary importance:—the need of the country, the range of benefit that the proposal will yield, its feasibility and permanency, and the remitting nation's fitness in promoting the consequent scheme.

China's Crying Needs

China certainly has many needs. But all will readily agree that the lack of an adequate and efficient public health service is one of the crying needs, if not *the* crying need, of China to-day. One does not have to go far in order to be convinced of this; the health of the people, the general sanitary conditions, the high infantile mortality and the recurring epidemics are sufficient to prove to the Chinese themselves how dire the need is. It is true that health conditions in the different foreign concessions are much better, and that Western missionaries have helped to initiate certain needed sanitary reforms in and around their stations. During recent years the Chinese Government has also undertaken to improve the living conditions in the large cities. But these efforts, worthy as they are and made under such unfavourable conditions, amount to almost nothing when we take into consideration the vastness of the country and its tremendous population. The need still remains great.

Indemnity funds used in the promotion of public health will not only meet the crying need in China, but will also affect the greatest number of people. Improved health conditions in China do not affect the Chinese alone although the Chinese form one-fifth of the world's population. Besides the Chinese, there are also thousands of foreigners residing in various parts of the country whose lives and properties will certainly receive the full benefit. Foreign trade in the country will be stimulated which means more foreign population in China. Moreover, the backwardness of China's health conditions has often been the cause of her sons and daughters being unwelcome to foreign countries, sometimes leading to unpleasant international relations and regulations. The periodic epidemics have frequently and seriously affected trade coming into and going out of the country on account of the quarantine regulations. Better health conditions in China will, therefore, benefit the whole world in more ways than one.

The feasibility of the few major proposals have often been questioned. Many doubt if those proposals are capable of being carried out and, if carried out, no one can guarantee that they would not be misused by the politicians and militarists who are and will be dominating this country for some years to come. Then it will simply mean the creation of more troubles for the people, plunging the country into deeper misery. The work of promoting public health is, however, primarily humanitarian in nature. The work can easily be organised in such a way and with such a personnel that political and military interference can be avoided. Certainly, public health promotion, thus organised and conducted, can never be used by politicians and militarists as a weapon to injure the people and the country. Under the present abnormal conditions in China, which are sure to continue for some time, this proposal does seem to be the most feasible.

Permanency of any proposal should certainly be one of the deciding factors. The funds available are limited in amount and cannot form a perpetual source of income. If not judiciously used, they may soon be exhausted, rendering it impossible to continue the work, whatever it may be. Should it come to that, this would be quite a calamity indeed. However, in promoting public health measures in China, the work can be so carried on that its permanency will be assured. For example, part of the money might go to defray the expenses in training the necessary personnel in the medical schools of good standing in this country; part of it might go into the expenditure of general administrative purposes; part of it might be spent in the actual work of promotion, such as the giving of public health demonstrations, work of research, and subsidies and loans to those agencies, either Government or private, whose efforts along the line of public health deserve help and encouragement; and last, but not least, an adequate part of the fund could be reserved as a sinking fund, which would enable the work to go on indefinitely.

A Public Health Ministry

As to Great Britain's fitness in promoting public health in China, none will question her qualifications. She is the pioneer in placing public health definitely on a governmental basis by the establishment of a Ministry of Public Health. Her efforts and experiences in improving living conditions in her several colonies make her an expert along these lines. Her medical representatives in China in the past half a century have always taken a prominent part in helping China to solve her health problems. With her wide experience and deep interest in the work of public health, it is only fitting, yea even imperative, for her to assist China in instituting a modern and efficient public health service. And Great Britain is pre-eminently fitted to do it.

In these days of agitation against British imperialism, boycott against British goods, and popular outcry against "the British domination," it is most urgent for Great Britain to do something to show unequivocally to the Chinese her true spirit of the Samaritan. The best way, it seems, is for her to take a prominent and active part in promoting public health in China. As already indicated, the work of public health is primarily humanitarian in nature. It aims at the relieving of the sufferings of the people which cannot fail to touch the hearts and win the goodwill of the masses. Once the people's heart is won, all material benefits from trade, business, industries, and what not will naturally come to her.

If we come to consider the sources from which the Boxer Indemnities are collected, it is almost obligatory for the authorities concerned to use the funds in such a way that the resulting benefits will spread all over the country. No plan can be justifiable if its benefit is restricted to only a small area of the country, and if only a small proportion of population are directly affected. For it is the entire population of China who are the contributors to the Boxer Indemnity chest, not a particular section nor a portion of the population of the country. It is true that a well-planned scheme, properly carried out, will eventually benefit indirectly the whole country. Since all Chinese are contributors to the Boxer Indemnity Funds, such funds, when remitted to China, ought to be used in such a way that it will affect the whole country directly and as soon as possible. The promotion of public health in China is precisely the plan that has already been pointed out in the foregoing paragraphs.

Finally, it may not sound too exaggerated to say that, of all the professions, the medical profession, by the very nature of its training and work, contains the least number of men whose aim of life is purely for personal gains. So much can certainly be said about the properly trained modern medical man in China whose technical training and personal character is uniformly high. Given for the purpose of promoting public health in China and entrusted to such a body of men, both Chinese and foreign, there is no doubt that every penny of the funds will be well spent, and that the work to be established will be honestly and efficiently carried on.

Mutual Benefit

In conclusion, one important phase of this problem in spending the funds which has already been pointed out by different authorities and leading papers, may be considered The word "mutual," contained in the resolution of the British Government concerning the use of her Boxer Indemnity may give the impression that, after all, the funds are to be spent mainly for the British interests in China, which evidently is not the sole motive that prompted the British Government to perform such an unselfish deed to China In the final decision on how the funds are to be used, we may with all true friends of Britain reasonably hope, that not only the words will show Britain's real unselfish spirit behind the act, but that the nature of the controlling personnel and organisation will also prove to all that the funds are to be spent for and by the Chinese with expert British advice and support only Funds so used and controlled, although entirely for China's benefit, will, as already pointed out, inevitably result in Britain's benefit, too So let it be a free gift to the recipient, and let whatever fall to the giver come as a matter of course

Viewed, then, from all angles the allocation of at least a portion of the British Boxer Indemnity for the promotion of public health in China is the best, wisest, and most feasible way for Great Britain to render an everlasting service to China in the latter's days of trial and turmoil The leading medical associations have jointly made such a proposal to Lord Willingdon's Commission Following that, they have presented to the same delegation a tentative plan, and later on a detailed plan, embodying all phases for the carrying out of their proposal All these go to show that members, both foreign and Chinese, of those associations are public spirited, serious-minded, and thoroughly earnest Let us sincerely hope that a proposal of so much value, supported by such enthusiastic spirit and united effort, will have the primary claim on the attention of the Statutory Committee, before the final decision is reached

ROWLAND HILL AND VACCINATION

Christ Church, Westminster Bridge-road, which celebrated its jubilee from July 4th–6th, is a perpetuation of the work of the Rev Rowland Hill at the famous Surrey Chapel in Blackfriars-road, where for 50 years he drew crowded congregations of all classes Amongst Hill's many interests was vaccination, and he was a staunch friend of Dr Jenner Frequently after his sermon—and he is said to have preached 23,000 of them—he would say, "I am ready to vaccinate to-morrow morning as many children as you choose, if you wish them to escape that horrid disease, small-pox you will bring them" At the Old Surrey Chapel he established what would to-day be called a vaccination clinic and he must have vaccinated 10,000 people

Hill was buried under the pulpit at Surrey Chapel, but when, under Dr Newman Hall the congregation moved to Christ Church 50 years ago, his body was removed to the new church by special permission It still lies under the old pulpit that stands to-day beneath the Lincoln Tower This tower, largely built with American money, commemorates Dr Newman Hall's championship of the North during the American Civil War Christ Church, Westminster Bridge-road, is also associated with David Livingstone, who was a friend of Hall's, and a vestry is named after him, which contains, besides Rowland Hill's relics, two cases of Central African insects presented to the church by Livingstone

GUARDIANSHIP SOCIETY

THIS society, which has its headquarters at Brighton, arranges for the care of the subnormal in body or mind and boards out suitable cases under supervision and guardianship It has been in existence for 13 years During 1925 514 cases were dealt with, which was an increase of 23 per cent, and the expenditure was £13,482, as against £10,417 in 1924 There has been an increase of 100 per cent over the previous year in the number of patients received on licence from certified institutions The society continues to do good work at its cottage farm at Dungates, Horeham Road, and at Beadles Cottage, Cowbeach, both in Sussex, and in coöperation with the Brighton Corporation and the Mental Hospital it has now formed a mental after-care committee

AN ARMY SANITATION HANDBOOK

"SANITARY measures must be, firstly, *understood*, secondly, *believed in*, thirdly, *practised* by every officer, non-commissioned officer and man" These are the fundamental principles of the "Army Manual of Sanitation"[1] which is designed to explain sanitation, and especially army sanitation, to regimental officers and men, as it very well does The soldier's health is good unless it is upset and so the handbook tells him what to avoid, and in detail what arrangements the army makes to help him to keep down flies, to get clean water and food, to breathe pure air, and to avoid infection It also tells him what will happen if he neglects its instructions, putting prominently before him its plea for the persistent personal practice of prophylactic precautions, and assuring him that if he and his mates get ill, it will be largely through their own carelessness Moderate tobacco smoking is described as probably beneficial, and alcohol, "though not a necessity," is not condemned The remarks on disease vectors are excellent, but surely the fact that lice are "now" known to carry disease has not made personal cleanliness more important "than it was formerly," but only more important than it was formerly thought This book is very good and very cheap, laymen could read it with pleasure and profit

EXPERIMENTAL OPOTHERAPY IN FOWLS

IN the *Semana Medica* (April 22nd, 1926) Dr Pablo Heredia describes some experiments in which he fed healthy male chickens on varying quantities of bovine testicular extract and observed the effect on growth and the development of secondary sexual characters

The chickens were taken in pairs, one in each pair being a control, and the birds were as nearly alike as possible, each pair being taken from the same brood The results were the same in all cases The untreated bird developed better than the other, and on post-mortem examination the testicles of the birds fed with extract showed some congestion and degeneration of cells, the results being roughly in proportion to the amount given

The author concludes that so far as these experiments go, they show (1) that opotherapy is incapable of exciting glandular action, (2) that it supplements the function of the gland treated, (3) that it inhibits the glandular secretion when its action is prolonged and may produce glandular atrophy Possibly it has some toxic action He admits that these conclusions are only provisional and that much more work is needed to make them certain, in any case they only relate to the effects observed on glands that are primarily healthy and in the developing stage, and have no bearing on morbid conditions They do, however, suggest that testicular extract from one animal has a specific effect on the testes of another and on the secondary processes connected with them, and it is interesting that this should be true when the animals are so distantly related as bulls to chickens

THE CANTAB IN 1826 [1]

IT has occurred to Mr Teichman that, owing to the great social changes which have taken place in the life of the undergraduate at Cambridge during the past 100 years, some account of that young man in the 'twenties would be interesting He has therefore, compiled a modest little book illustrating mainly the sporting side of undergraduate life, but including interesting chapters on other phases A small bibliography shows the principal sources of the compilation, and explains also a feeling which many Cambridge men will have on reading the book—namely, that the revolution in manners and outlook has occurred largely at the end of the century under consideration For, allowing for minor differences, much that is described as occurring 100 years ago also occurred 50 and even 40 years ago, the episodes were not identical, but the spirit behind them had persisted and the traditions, leading to the similar occurrences, were going strong This can be recognised in the amusing chapters entitled "The Boating Man," and "The Sporting Man" At the same time it can be seen that the nature of the fast man's excesses had changed considerably between Georgian and mid-Victorian times, in sympathy with improved standards of conduct and an alteration for the better in social opinions This evolution rather than revolution of manners comes out the more clearly because the author, as he acknowledges, while professing in his title to deal with Cambridge 100 years ago, has been lured forward into the 'forties by some of the literature which he has consulted The chapter entitled "Town and Gown" is not descriptive of anything that has been seen for more than 50 years, but readers of *Verdant Green*, whose adventures took place at Oxford, will recognise that at one time there was a real feud between the university undergraduates and a certain type of citizen, boasting Rogue Riderhood's appellation of "waterside character" We doubt if any one alive can recollect the existence of this feud as having any real basis, though traces of it could be found 40 years ago, while sentiments exactly opposite now prevail between townsmen and gownsmen

ON THE

INSULATION OF THE NERVOUS SYSTEM

Delivered at the House of the British Medical Association on July 9th, 1926,

BY WILFRED TROTTER, M S LOND , F R C S ENG ,

SURGEON, UNIVERSITY COLLEGE HOSPITAL

WITHIN a few days it will be exactly ten years since Victor Horsley died The circumstances of his death, however lamentable they may seem to us who lost him, were not perhaps, very different from what he himself might have wished He was at work in the direct service of his country ; he was using his whole strength in the relief of suffering, while his mind and body kept unabated their astonishing and characteristic vigour In commemorating this great man our attention is attracted to three separate aspects of his life We think of him as a physiologist and as a surgical pioneer, and we think of the personality which lay behind and informed these and all the activities of his crowded years

His work for science and for surgery has long been incorporated with the general body of knowledge and has its lasting place For his personality there is no such lodgment and those in whose memory it lives so vividly are already, after the passage of even ten years, a heavily reduced company I therefore gratefully accept this chance to make my small record of a man who, in my knowledge of men, was unique in this, that he combined an inflexible belief in his own standards and a truly apostolic zeal in all public affairs, with a disposition that was in its essence boyish and simple and in every private relation easy and mild and kind

METHODS OF INVESTIGATION IN NEUROLOGY.

The pioneer work of Horsley in the surgery of the central nervous system has had, and must continue to have, remote and secondary effects upon the development of neurology Whenever a region of the body has been made accessible to surgery, a new insight into its pathology has resulted from the fresh experience that has been acquired of morbid processes in the living and especially of the earlier stages of disease This has been abundantly shown in the case of the abdomen and in the case of the thorax In that of the central nervous system it is, perhaps, as yet less obvious, but it is already unmistakable and will become increasingly so as experience accumulates

While most of us would no doubt agree that important practical knowledge is to be acquired in this way, there are probably few who look to it with much hope for the discovery of principles of general scope and fundamental significance As a possible source of any wide expansion of neurological theory it is just and natural to look to laboratory methods and the study of animals rather than to methods of the bedside and to the study of man himself in his reactions to injury and disease In the familiar and not always philosophically made comparison between the experimental and clinical methods, it is usually, however, overlooked that the latter has of necessity a virtue which is in some degree its special possession The student whose material is man is drastically handicapped by the limited extent to which experiment is open to him He must take his problems as he finds them and deny himself the help of almost all the preliminary simplifications which are the essence of the laboratory worker s advantage At the same time however the conditions of his work impose upon him a knowledge of his material at once so intimate and so wide as to constitute a situation probably unique in the whole field of science When we consider the intensity of watchfulness which the quite ordinary practice of neural surgery calls for and obtains it must be obvious that the behaviour of the human brain in the various circumstances of injury and disease is far better known than that of any other animal. Indeed one of the characteristic difficulties of the clinician comes from this very abundance of the stuff of observation, and he is likely to be overwhelmed by its bulk and rendered inattentive by its familiarity, losing amongst details his sense for larger groupings, and amidst the everyday his eye for the significant Nevertheless, the history of science shows that one important source of general ideas has been just this very circumstance of a close intimacy with a large range of observed facts

The familiarity with the behaviour of the central nervous system that has been possible since it has been accessible to surgical exploration and treatment, is capable of reacting in an important way on our attitud to neurological theory

THE ABSTRACT METHOD IN NEUROLOGY

There are few departments in biological science in which what we may call abstract methods of thought are more naturally and inevitably used than they are in neurology By abstract methods I mean methods in which the single or grouped items of experience are for convenience of thought represented by abstracted summaries of themselves or symbols which have a handiness for working on in the mind that the raw undigested facts cannot possess The discovery of the uses of abstraction was an event of fundamental importance in the evolution of science, and in the early Greek natural philosophers we can see with what exultation was welcomed the extension it gave to the powers of the mind Perfectly legitimate and indeed indispensable as the method is, it is obviously not applicable to all material of inquiry with equal ease and safety With what certainty and precision the qualities of number, space, and motion allow of abstraction is seen in the noble achievements of mathematics, physics, and astronomy achievements which through their most recent extensions in atomic and in stellar physics have finally established the overwhelming prestige of the method and its effective leadership in science

When, however, we make living matter and living organisms the subject of study, we find, though we can by no means dispense with the use of abstraction it is far less effective in application and has disadvantages which it does not seem to possess in the inorganic world In biological inquiry an abstract conception, though professedly no more than a convenient summary of experience and constantly subject to the censorship of facts, is apt to acquire a quasi-vitality of its own through which it loses its immediate dependence on experience and comes to *dominate* instead of serving The danger arises not so much from the extreme cases of conceptions which easily show as flagrantly inconsistent with facts but from ideas primarily good and sound which have been endowed with a prestige that in their very nature they could not deserve That an over-valuation of the abstract conception as an implement of research can deceive even the very elect could be shown by many eminent examples The biological writings of Herbert Spencer are perhaps, as good an instance as comes readily to mind, and it is easy to trace in them how this very weakness has led within a few years to their greatly diminished influence. To find so distinguished a man in a state of reprobation may well make humble people look anxiously to their own doctrines and indeed which of us for example, can ask himself without a qualm what is the *exact* meaning he attaches to the abstract conception of evolution which has dominated the biological world for half a century

When we turn to neurology, we find the currency and influence of abstract conceptions very great as for example, in the theory of aphasia in Hughlings Jackson s interpretation of cerebral functions, in Monakow s doctrine of diaschisis and so forth All these are doubtless in their essence and originally, good and valuable conceptions It is another matter, however, how far their function as professed summaries of experience is kept distinct from their charm as mere intellectual patterns It is thus peculiarly necessary for neurology to submit itself to the discipline of frequent returns to the comparatively primitive and clumsy method of direct and concrete thinking Such efforts should, I think, be guided by two principles The first is the obvious one that a constant and docile reference to experience is indispensable The second is, perhaps, less obvious and is less simple to state, it accepts the free use of hypothesis as essential to neurological progress, but it enjoins, that in drawing up our necessarily more or less abstract conceptions of the nature and working of the nervous system, we should incline to the use of ideas of a definitely biological type and should, as far as possible, avoid concepts that in their very nature can have no direct resemblance to what actually happens in the body In giving to our neurological ideas this concrete and realistic tone we shall always depend to a great extent on an intimate familiarity with the appearances and behaviour of the actual nervous tissues The knowledge of this kind we possess to-day may well be regarded as having in great part grown out of Horsley's work

The surgical neurologist is perhaps fortunately placed for considering the nervous system in an attitude of mind at once general and concrete, while he lacks the special knowledge of the anatomist, the physiologist, and the pathologist he is also free from their special preoccupations, while the behaviour of the nervous tissues in injury and disease is a matter of familiar knowledge it is prevented from becoming commonplace by the narrow margin of safety within which he works and the serious consequences that follow when it is exceeded Thus is almost forced on him the development of views which, whatever they may lack in the way of abstruse detail will, at any rate, always tend to be strictly realistic

INJURIES TO THE LIMITING STRUCTURES OF THE NERVOUS SYSTEM

In illustration of this general point of view I propose to call attention to a small group of facts which, while they are of more or less common knowledge, are perhaps more especially within the observation of the surgeon They are concerned with the responses of the nervous system to certain injuries

Division of a Nerve—It is a very old observation that when a mixed peripheral nerve is cut its central end becomes swollen into a bulbous mass of dense fibrous tissue It seems sometimes to be thought that this is only an occasional result of a nerve section, and is especially to be looked for when persistent pain has followed the injury This is, of course, not the fact The bulbous end is the invariable and inevitable result of a nerve section to which it is the necessary and, so to say, physiological response When we inquire into the exact nature of this so-called amputation neuroma we find that in immediate consequence of the section the nerve-fibres ramify and grow out from the cut end so that there issues from this a veritable spray of fine naked axis cylinders The result of this invasion is to call forth an energetic response from the adjacent non-neural tissue leading to the formation of a peculiarly dense fibrous material that resists the spread of the nerve fibrils and finally encloses them in an impenetrable capsule Within this limiting substance the growth of axis cylinders continues, but since there is no exit it can result only in the formation of an intricate and aimlessly convoluted network

Breaches of the Spinal Theca—It occasionally happens, usually, perhaps, in connexion with the avulsion of a spinal nerve, that a subcutaneous laceration of the spinal dura occurs More commonly the surgeon has an opportunity of studying the effect of breaches of the theca in cases where a laminectomy with incision of the membranes has to be followed by a second similar operation after some weeks or months We find then that wherever the cerebro spinal fluid has been able to escape into the tissues it has been everywhere walled off by a dense impervious membrane so that, according to the extent to which the fluid has made its way, there will be a more or less complicated series of cyst-like spaces communicating with the intrathecal cavity It is the wall of these cystic extensions of the theca that is of interest, for it shows all the characters of the normal dura It is of a dense fibrous substance, its inner surface is smooth and glistening, and its outer surface, instead of merging with the surrounding tissues like a scar, is easily separable from them along a well marked line of cleavage

Regeneration of the Cerebral Dura—It is not uncommon for a second cerebral operation to be necessary in a case in which the dura mater has already been opened or removed If the second operation is done after an interval of about six weeks or more it will be found that the gap, however large, that was left in the dura at the first operation has been closed by the formation of a new membrane having all the characters of normal dura as above described Among such characters the most striking, and perhaps the most conclusive of the nature of the new membrane, is its differentiation from the overlying scalp, so that the latter can be stripped away from it with ease and without bleeding It is interesting to note that at one time a great deal of surgical ingenuity was expended on evolving a plastic surgery of the dura in which gaps were closed by the insertion of fascial grafts Such grafts were always remarkably successful because a new dura would have formed quite naturally and equally well without them

Here we have a group of three well-defined facts established by countless observations and capable of confirmation at any time They bring evidence from different parts of the nervous system disclosing even to superficial consideration a clear common tendency The conclusion to which all point is that breaches of the normal coverings of the nervous tissues allowing contact between the latter and other tissues of the body result of necessity in energetic local reactions The obvious function of such reactive processes is to re establish the normal discontinuity between neural and somatic tissues and to break the contact that has caused the disturbance

We have met then, with a mechanism of a definitely physiological type which may well prove to be concerned with the very nature of the nervous system Our next inquiry will naturally be what is the immediate agent of the reaction we are concerned with In the case of the divided nerve it seems clear that the escaping naked axis cylinder is the actual irritant substance, in the case of the spinal theca it is evident that the cerebro-spinal fluid is the effective agent, in the case of the cerebral dura it is probable that in ordinary conditions with an intact arachnoid, fluid exuding through this is the excitant, though the contact of the brain itself is doubtless also effective It is seen then, that there is a common property possessed by naked nerve-fibres, by cerebro-spinal fluid, and almost certainly by the brain substance itself, which enables these to set up in the somatic tissues an energetic reaction the tendency of which is to insulate the one from the other There is evidence that the neural side of the contact while effective as an irritant, does not contribute to the newly-formed tissue which, whether in the form of the fibromatous material of the bulbous nerve or in that of the extemporised dura is of purely non-neural origin and though obviously a highly specialised material and no mere scar

FUNCTIONAL EFFECTS OF BREACHES IN INSULATION

When we see such well-defined mechanisms for the sealing of breaches in neural insulation we naturally should expect to find such breaches to be of great functional importance and capable of causing serious disturbance in the tissues unnaturally brought into contact There is, in fact evidence that some effect on function is produced, but it is not to the mere prevention of this that we can look to explain the actual existence of these mechanisms themselves; that seems to depend, as we shall see, on some far more fundamental causation. The chief evidence of disturbed function is seen in the case of the divided nerve. Here there are symptoms suggesting persistent excitation of the cut end. These are always present from the first, but they vary greatly in intensity. The sensation of the presence of the limb after an amputation is universal, and it always lasts for several weeks. Not uncommonly it is painful, and then it tends to be more persistent and may last for years. The facts suggest that the exposed nerve-fibres of the stump are excited by contact with the tissues, and that in the bulbous end the stimulation effect gradually dies down until a state of equilibrium is established in which the new tissue sealing off the nerve end is practically as inert towards the nerve as is its normal sheath.

It is natural to suppose that, after a wound of the brain which allowed a scar of non-neural origin to come into close contact with the brain substance, a state of excitation might be set up. The frequency of traumatic epilepsy in cases of direct scarring of the brain is perhaps suggestive, but I know of no evidence that allows us to take the case beyond a mere suspicion.

On the somatic side of a breach of neural insulation there is no disturbance of function beyond the mere reaction already described. It is indeed characteristic of this that it is always and only strictly local. There is nothing in the way even of a diffuse or spreading fibrosis, the new tissue, whether it be an amputation neuroma or a new segment of dura, and although it is of somatic origin, becomes sharply differentiated from the tissues it is derived from and can be separated from them easily without cutting. We see therefore that although breaches of neural insulation are immediately dealt with by energetic, effective, and highly specialised mechanisms, the actual disturbances of function produced by such breaches do not seem to be very important.

INSULATORY ARRANGEMENTS IN THE NORMAL NERVOUS SYSTEM.

If the evidence I have cited bears the meaning I have given it, and we can regard as of high importance to the body the maintenance of neural insulation, then we can look for confirmation in normal structure and expect to find dispositions in relation to the nervous system which are insulatory in function. From the nature of the reaction we have seen to be set up by breaches of insulation we may infer that the influence against which insulatory mechanisms are provided is chemical in kind, and this inference may serve as a guiding principle in the search.

Insulation of the Peripheral Nerves.—Beginning our survey with the peripheral nerves we may at once dismiss from consideration the medullary sheath, which, whatever its physical insulatory function may be, is clearly not in question as a chemical insulant, since non-medullated nerves lie as peacefully and as inert in the tissues as the medullated. The case is different, however, with the neurilemma. Here we have a sheath common to all nerves outside the central axis and continuous without a break from spinal cord or brain to end-organ. The motor nerve-fibre is clothed from within the central nervous system to the muscle-fibre, where the neurilemma completes the sealing off of unnatural contacts by becoming continuous with the sarcolemma itself. The sensory fibres are similarly clothed throughout their length; at their peripheral termination they enter end-organs, all of which throughout a great variety of structure show—with one suggestive exception—so marked an encapsulatory arrangement that one cannot but think that here the need for insulation must be especially vital. The one sensory nerve-fibre which is known to terminate in an end-organ which is not of a strongly capsular type is the fibre that serves the sense of pain. This fibre ends in a free arborisation in the tissue to which it is distributed, and this terminal part is uncovered by neurilemma. It cannot but strike us as significant, though I shall not take up the point further at the moment, that this anomaly of a sensory fibre making naked contact with the somatic tissues should be a character of the fibre concerned with pain, a form of sensibility that in itself is so profoundly anomalous.

The view that the neurilemma is the chemically insulating structure we are looking for is confirmed by the fact that within the central nervous system, where insulation is otherwise provided, it is defective or altogether absent. A point further suggestive of the importance of insulation in the peripheral nerves is the evidence we have that there is an upward drainage along their trunks, so that the products of their metabolism are probably kept from contact with surrounding tissues and are conveyed into the central theca.

Insulation of the Central Nervous System.—When we turn to the central nervous system we find that the method of individual insulation no longer prevails, but that the whole mass of the central axis is protected as one unit. Plainly, of course, it is the meninges which are chiefly concerned. Of these we have already seen that the dura has so important a function that accidental defects in it are repaired with very remarkable rapidity and completeness. The *mechanically protective* function of the dura which doubtless has its importance can scarcely be regarded as explaining its peculiarly impervious texture, its double endothelial surface, and the marked line of cleavage that separates it even when newly formed from the surrounding tissues. All these, however, acquire meaning when they are regarded as evidence of its *chemically insulatory* capacity. Effective as the dura doubtless is in its way, it deals only with one relatively small part of the problem of insulation. If we are right in supposing that all neuro-somatic contacts are inadmissible, and that the blood and blood-vessels belong to the somatic side of the frontier, the nutrition of so large a bulk of nervous tissue as the central nervous system must involve dispositions altogether unique in the body, and we should expect in regarding the circulatory mechanisms of the part from this point of view to meet with features of a very special kind.

The cerebro-spinal fluid and its circulation, the existence and disposition of the multiple membranes of the brain, and the absence of a recognisable lymphatic system in the ordinary sense of the term, constitute a picture which is unique and has admittedly defied thorough explanation. Let us consider it in relation to the avoidance of undue contact between neural and non-neural elements.

THE CEREBRO-SPINAL FLUID.

Let me briefly review the strange facts of the physiology of the cerebro-spinal fluid as they are now known. The cerebro-spinal fluid is an extremely dilute secretion profusely poured out by the choroid plexuses of the cerebral ventricles. It flows through the central cavities of the brain and issues therefrom through the roof of the fourth ventricle into the subarachnoid space. Through this so-called space, which has rather the structure of a cellular spongework, it courses partly into the spinal canal, but chiefly upwards and forwards over the brain to escape into the venous circulation through the arachnoid villi that project into the various lateral extensions of the superior longitudinal sinus. As is well known, any obstruction to the flow in any part of this intricate course downwards within the brain and upwards outside of it inevitably leads to an accumulation of the fluid and to hydrocephalus. Such obstructions are easily produced and common. The cerebro-spinal fluid with its circulation, whatever function it may be there to perform, shows itself thus to constitute a weak spot in the cerebral organisation that as it were invites pathological attack. That the cerebral apparatus should contain an arrangement in some ways so seriously disadvantageous suggests that the mechanism *must* have some deep functional significance that is indispensable to the physiology of the body.

There is no lymphatic system in the ordinary sense in the brain or spinal cord and no flow outwards through the cerebro-spinal envelopes of anything corresponding with lymph occurs anywhere. It seems clear that products of nervous metabolism find their way into the cerebro-spinal fluid in the subarachnoid space; there is, in fact, strong clinical evidence that this fluid has a definite toxicity for the rest of the body, for when it is liberated into the tissues high fever is apt to occur during the short period before absorption is arrested by the inevitable reaction in the tissues that produces encystment. It is thought that metabolic products reach the cerebro-spinal fluid along the so-called perivascular lymphatics. These remarkable structures are tubular extensions of the subarachnoid space which accompany and enclose the vessels that penetrate the brain to their finest ramifications. The interpretation of their meaning has long been regarded as a great difficulty, but if we accept the view that somatic structures like the blood-vessels cannot be admitted to direct contact with the nervous tissues it is natural to regard the perivascular lymphatics as mechanisms to insulate the blood-vessels from this contact. It may be assumed from what we know of the nourishment of tissues in general that there is some kind of leakage from the cerebral tissues comparable with lymph as found everywhere else and presumably of a not dissimilar concentration. This fluid will find its way to the subarachnoid space presumably by the perivascular channels. The disposal of such a material may well be regarded as an exacting task. It is impregnated with products of nerve metabolism and is an eminently "neural" fluid capable of producing energetic reactions in any somatic tissue it meets. Thus there can be no question of its entering the blood stream in the relatively high concentrations that are satisfactory for lymph, and Nature meets the case by providing for it being heavily diluted before it is allowed to join the somatic blood in the cranial sinuses.

The most characteristic feature of the cerebro-spinal fluid as it exudes from the choroid plexuses is its remarkably low solid content. It is by far the most watery secretion produced by the normal body, and one might almost say it is an attempt by Nature to secrete pure water. It contains a small amount of the diffusible substances of the blood, but practically nothing else. So strong is the tendency to keep the fluid watery that the choroid plexuses have a truly astonishing impenetrability to drugs and other foreign substances circulating in the blood. Even the bile-pigments in cases of jaundice fail to find a passage. This fluid, practically amounting to nothing but water, is secreted in large quantities; on rare occasions I have had the experience of seeing as the result of accident what was, perhaps, a large fraction of the total secretion of cerebro-spinal fluid discharged on the surface. The amount of fluid escaping has been very large and the consequent inanition correspondingly profound. The normal function of this great flow of water we may suppose with some confidence to be to flush through the whole subarachnoid space and to dilute the products of cerebral metabolism to such a degree that the resulting fluid can be safely admitted to the general blood stream. This view gets some confirmation from the evidence we have that the fluid in the subarachnoid space has a larger solid content than the fluid in the ventricles.

It is interesting to reflect that the source of this mysterious secretion which has given so much difficulty to the chemical physiologist may turn out to be no more abstruse a thing than Nature's nearest approach in the animal body to a spring of plain water; if this should be so it may also remind us of the small and amusing coincidence that one part at any rate of the tortuous channel through which the fluid runs—the *aqueduct of Sylvius*—has since the very early days of anatomy borne a singularly exact and appropriate name.

In our review of certain aspects of the nervous system we have found reason to regard as of fundamental importance the preservation of an impenetrable barrier between the whole of the nervous system and the rest of the body. This barrier we have seen to be made up of a number of highly special structures and mechanisms. Its function is, on the whole, to prevent contact between the neural and the non-neural, but is also in certain places to permit it. These places are only two: first, where the motor nerve-end comes into contact with the muscle-fibre, and secondly, where the naked arborisation of the pain nerve meets the tissue in which it is distributed. The nervous system is thus kept apart from the body, as we may say, in order that when the two are permitted to meet the reaction shall be the more energetic. It is in fact, then, of the very essence of nervous tissue that it should be different from the other tissues so that it can irritate and be irritated by them. This necessity for a certain "strangeness" of the nervous system may possibly throw some light on its curious embryology. The origin of the nervous system as an epiblastic tube originating on the surface of the body and then sinking into its substance has been investigated chiefly from the morphological point of view, and great ingenuity and research have been expended on it. It may be worth suggesting, however, that the problem has also a functional side, and that the epiblastic origin of an organ that is ultimately to be deeply embedded in mesoblastic tissues possibly has the function of contributing its strangeness and, therefore, its effectiveness to the nervous system as a whole. This quasi-hostility between neural and somatic, between brain and body, is a suggestive and perhaps a disturbing thought, but we shall not attempt here to follow it out.

Neural Insulation in Pathology

It is more convenient at the moment to consider certain pathological evidence that has some bearing on the conclusions we have already reached. That the central nervous system differs from other organs in having a certain inaccessibility has long been recognised in connexion with syphilis. The difference between the strictly extraneural mesoblastic infection of the meningeal gumma on the one hand, and the intraneural parenchymatous infection of general paralysis on the other, shows that the frontier between the two regions is as sharply marked pathologically as it is physiologically. Moreover, the relative inefficacy of antisyphilitic treatment in the parenchymatous infection reminds us that the frontier is also impassable for many drugs.

The dura and arachnoid are in some sense intermediate tissues for they show a certain tolerance for both neural and non-neural contacts, the arachnoid having slightly greater affinities for the former, and the dura perhaps for the latter. That they are, however, fundamentally non-neural in their behaviour, and probably also in their nature, is suggested strongly by their relations to certain tumours. The glioma is probably the one truly neural tumour that affects the central nervous system. Although it behaves within the brain as a malignant infiltrating growth, its spread is restrained by the neuro-somatic barrier, so that while in exceptional cases it may affect the meninges and skull by pressure atrophy it can never invade them or extend to the tissues of the body. On the other hand, the so-called "dural endothelioma" which is relatively so common as a growth involving arachnoid and dura, frequently shows the power to infiltrate the skull and overlying parts as a malignant neoplasm; but although it may press deeply into the brain it never invades it, being restrained as effectively in the one direction as is the neural glioma in the other. The behaviour of these two tumours has long been familiar, but seems always to have been accepted as very much a matter of course. It is perhaps more reasonable to regard it as one of the most significant anomalies in the whole of pathology.

Our final pathological illustration takes us back to the peripheral nerve. We have already seen that this is the only part of the nervous system where a breach of insulation produces immediate and definite disturbance of function The neurilemma seems fortunately, however, to be an exceedingly effective barrier between neural and somatic tissues There is clinical evidence that a relatively slight subcutaneous injury can lead to the formation of a neuro-fibroma presumably through damage to the neurilemma, but this is a rare event of little practical importance, and failing gross injury the insulatory mechanism is wholly satisfactory That this is the result of effective restraint rather than inertia on the side of the nervous system is perhaps shown by that fortunately rare complaint multiple neuro-fibromatosis or Recklinghausen's disease In this condition it has been shown that every fibromatous formation, localised or diffuse, contains nerve-fibrils which presumably by their irritant qualities have given rise to the fibrosis much as might a foreign body or a micro-organism of highly attenuated virulence. It seems clear that it is the presence on a large scale of nerve-fibrils outside their normal insulating sheath which is the proximate cause of the morbid state. It may be doubted whether the neural leakage is a primary manifestation or is due to an essential weakness or collapse of the insulating function of the neurilemma. Whether the failure of this sheath is primary or secondary, absolute or relative, no one who has seen a severe case of the disease can doubt that any general collapse of the peripheral insulatory mechanism makes the life of its unfortunate subject almost insupportable.

INSULATION AND THE PHYSIOLOGY OF PAIN

I have already called attention to the remarkable fact that there is one kind of sensory fibre which ends in a free arborisation in naked contact with the tissues. Our last task in dealing with the insulation of the nervous system is to examine a little more in detail the striking anomaly that in their end-organs the pain fibres make this unique exception to the rule that sensory fibres are insulated up to and including their end-organs

This anatomical uniqueness of the pain fibre in its end-organ is matched by the uniqueness of the physiological characters of pain sensibility, and it is very natural that we should desire to correlate these two anomalies Pain sensibility is remarkable in three respects, first in the quality of the sensation itself, secondly in its threshold of sensitiveness, and thirdly in the nature of its appropriate stimuli. (*a*) The *sensation of pain* is peculiar in that it has a sudden and as it were explosive way of bursting into consciousness, in that it calls urgently and often irresistibly for some kind of motor response, and in that it is in its very nature distracting so as to be incompatible with quiet contemplation or steady judgment (*b*) The *threshold for pain* stimuli is remarkably high, so that in comparison with other forms of common sensibility the stimulus has to be relatively energetic to call forth the characteristic sensation (*c*) The stimuli that call forth pain sensations are remarkable for being very miscellaneous In every other kind of sensibility but pain, the normal response is to a single well-defined physical change—pressure is evoked by weight, touch by movement, cold by loss of heat, warmth by access of heat The ordinary stimulants of pain, on the other hand, such as pressure, pin-pricks, cold, heat, and the electric current make up a thoroughly odd class the members of which show no common character They are all capable of producing the characteristic sensation before, and usually long before, an intensity of stimulation is reached that can be shown to be harmful. That many of the stimuli would be harmful in greater intensities can scarcely therefore be regarded as forming a common physical basis, but must rather be explained as merely a consequence of the normally high threshold

When we consider these peculiarities we can hardly regard them as those of a highly differentiated mechanism, but rather as those of one relatively crude All sensibility may well have been of this kind in organisms to which the distracting explosive qualities of the sensation would be no detriment. If we look upon the peculiarities of pain as an evidence of crudity rather than of differentiation it is relatively easy to correlate them with the uninsulated end-organ of the pain fibre which we must regard as less differentiated and cruder than the complex end-organs of the other fibres Pain sensibility would thus owe its special character to being the function of a nerve-fibre of a peculiar kind, which while relatively insensitive responds in an exaggerated way when its threshold is reached. Presumably these characters are to be associated with the uninsulated end-organ, and we may suspect that it is this lack of insulation which gives to the fibre its characteristic features of blunt sensitivity and emphatic response

We possess a possible source of further light on this problem in the phenomena that accompany the recovery of function in sensory nerves after division and immediate suture It is well known that this process as observed under experimental conditions in the human subject by at least three independent groups of investigators, is accompanied by remarkable modifications in all forms of sensibility. It is impossible to refer to these modifications in detail, but it gives them in a broadly approximate way—and I speak from actual personal experience of them—to say that they are generally in the direction of the peculiarities shown by normal pain; in other words, the modified sensations compared with the normal are more explosive and more urgent, they have a higher threshold, and they call for some kind of motor response. The explanation of these and the other modifications that are to be observed during recovery of sensory nerves has differed with different investigators. It is far too much a matter of detail to discuss these differing hypotheses here, but there is one criticism to be offered of some that is relevant to the general attitude we have tried to support This criticism is that there has been a tendency to approach the problem in too abstract a way. It has been assumed that the question is one of the mere return of functions that are present in the normal and in the form in which they are then present, modifications in the character of sensation being ascribed to such factors as the order of return and the rate of return of different functions, and the modification in character of one form of sensibility to the presence or absence of another This is to assume that the processes and incidents of regeneration itself have nothing to say to the problem; and that the struggle between the advancing nerve-fibres and the reaction they arouse from the line of suture onwards can be ignored To take it for granted that the naked growing fibres can pass through this difficult and prolonged ordeal without any alteration in their function. and to limit the problem in this way to strictly and exclusively neural factors seems to me a method less concrete and practical than the case demands

An alternative hypothesis. which is at any rate more comprehensive and more simple. can however, be put forward The general tendency of all forms of sensation yielded by a regenerating nerve to develop a certain resemblance to pain reminds us that regenerating fibres resemble pain fibres in a lack of complete insulation It is probable, therefore. that imperfect insulation tends to render all fibres less sensitive than normal but more apt when effectually stimulated to respond in an exaggerated explosive way With the advance of regeneration the fibres serving touch heat, and cold become once more connected with end-organs, and then their insulation by the junction of the neurilemma with the capsule of the end-organ can be completed. The completely insulated fibre, having lost its temporary resemblance to the pain fibre, becomes once more sensitive to the finer stimuli and ceases to yield exaggerated responses

The process of regeneration thus seems capable of causing a regression of function in all kinds of nerve-fibres to a cruder type that in the normal is represented only by pain This regression occurs because during regeneration insulation must necessarily be defective. According to this hypothesis normal pain and the sensibility of regenerating nerves give us an insight into the ancestry of common sensation Primitive sensibility of all kinds we may suppose to have been like pain in us, it had a relatively high threshold, but it was effective because its sensations were urgent and explosive and, of course (also like pain in us), were exactly localised Among such sensations fine discrimination was plainly impossible With the development of the completely insulated nerve and end-organ, the fibres thus equipped became capable of yielding sensation to finer and to specialised stimuli, and of a quality no longer explosive but able to be submitted to discrimination, at the same time the large number of pain nerves remained in their primitive state to warn the body of strong stimuli by urgent sensations, among which there was no power and no need for discrimination because their function was to excite immediate response

The great and manifest difference between the vertebrate and the invertebrate nervous systems is that the former is centralised and the latter is scattered throughout the body The facts I have quoted and the inferences I have drawn suggest the hypothesis that side by side with centralisation and rendering it possible, insulation also must have proceeded Insulation, on the one hand, must have been made increasingly necessary by the growing differentiation of neural from somatic tissues, and, on the other hand, must have helped to sharpen this very difference It is not, therefore, surprising that a function so fundamental is not only recognisable in the structure and behaviour of the normal nervous system, but is also evidently at work in morbid processes and constitutes at once a help and a limitation to the work of the surgeon

---

FURTHER OBSERVATIONS ON IMMUNITY IN RELATION TO TRANSPLANTABLE MALIGNANT TUMOURS.

By THOMAS LUMSDEN, M D. ABERD

(From the Department of Experimental Pathology, Lister Institute)

THE conclusions arrived at and reported in previous communications in THE LANCET[1] have been confirmed and extended The further experiments described below were mostly designed towards supplying an answer to the following questions —

(A) What is the nature of the antibodies which can be demonstrated to exist in the serum of an animal (e g, rabbit sheep, horse) which has been repeatedly inoculated with tumour cells from another species (e g, mouse, rat, man) ?

(B) When by treating one of two coexisting tumours both are caused to disappear, may we conclude that products absorbed from the regressing treated tumour effect the cure of the untreated tumour by giving rise to antibodies in the host's blood or tissues ?

(C) When an animal has been rendered resistant to a particular tumour wherein does its immunity consist ?

The methods employed in these investigations were (except where detailed below) those described in the papers above referred to

Antiserum Treatment in Vivo

To 50 rats bearing a J R[2] sarcoma of each hind foot, varying in size from a green pea to a haricot bean treatment was applied as follows —

In 38 rats 0 9 c cm of anti J R S serum was injected in three doses of 0 3 c cm each the circulation in the foot being coincidentally shut off by constriction at the ankle for 2–3 hours In all of these animals the tumour of the treated foot disappeared rapidly, while in 37, about 7–10 days later, regression began also in the untreated foot and went on to complete cure In one rat, probably because the treated tumour was too severely constricted, the untreated tumour grew progressively The fact that in these cases the untreated tumour only begins to absorb from 7–10 days after the cure of the treated tumour, indicates that the regression is not spontaneous but is due to treatment This view is corroborated by the fact that of the 50 control untreated animals only in five did the tumours regress Fig 1 shows the condition of the tumours in the last 24 controls when the experiment ended, it will be noticed that in all except two of these, progressive tumours have developed In 12 rats of this series of 50, cure was effected without constriction by means of repeated inoculations of antiserum into and around the tumour Of this dozen animals, in six the antiserum used was one made against mouse carcinoma (M_{63}) Even in these 12 rats it is possible that part at least of the curative effect was due to interference with the vascular supply, for not infrequently hæmorrhages occur into the tumour after the antiserum has been injected

In a previous paper[3] it was reported that after cure of their feet in the above way rats were found to be absolutely immune to the tumour concerned It is now possible to state that this immunity is of long duration A test inoculation was given to 50 rats six months after their recovery. Of these, only two developed progressive tumours, the other 48 were still completely resistant to a sarcoma which grew rapidly in all of 12 normal animals inoculated with identical material at the same time It must here be reiterated that *striking results can only be obtained by using a tumour of great virulence and in its most active phase*, otherwise so many of the control tumours might regress as to lessen the cogency of the experiment

In a large number of animals the attempt was made to cause the disappearance of tumours of each flank in the above way The results were not very satisfactory The tumours grow so rapidly as to cause death in three or at most four weeks Thus the untreated tumour attains enormous proportions before the regression of the treated tumour can influence its growth, by which time the defence mechanism of the animal appears to have broken down completely In the last 20 animals a second tumour was inoculated a week later than the tumour which it was intended to treat Of these animals, in six regression of the treated tumour was followed by absorption of the untreated tumour and the animals were thereafter found to be immune, in ten the attempt to cure the larger tumour failed and both tumours grew progressively, while in four rats the treated tumour was so severely constricted that it separated after a day or two and no effect was produced on the smaller untreated tumour *It appears that in order to effect cure and evoke immunity gradual regression of the treated tumour is essential*

Attenuation

Many attempts were made to attenuate J R S cells (by heat by cold, by autolysis, and by treating the cells in vitro with antiserum, &c), so that when inoculated into a tumour-bearing animal an effect comparable with that produced by gradual regression of one of two tumours should be obtained These attempts were unsuccessful Frequently attenuation was not carried far enough and a fresh tumour arose at the spot where the attenuated cells were injected Even when this did not happen not only was it found impracticable to cure an animal in this way, but the attempt to produce immunity to a subsequent test inoculation also failed The only successful experiment, inconclusive on account of the small number of animals used, was one in which J R S fragments coated with agar were injected into three rats bearing a tumour and into three healthy rats No curative effect was noticed but the three healthy rats were found two weeks later to be immune, while three control rats of similar breed, given a test inoculation with the same material, all developed progressive tumours This modification, suggested by Dr P Bruce White, will be repeated, using a larger number of rats

[2] J R S is an abbreviation for Jensen's rat sarcoma M_{63} for the mouse carcinoma, so named by the Imperial Cancer Research Laboratory

[3] THE LANCET, Sept 12th, 1925

A. *Nature of Antibodies Demonstrable in Heterologous Antisera*

In the attempt to elucidate this point a very large number of experiments have been made.

The following antisera have been produced and tested on many different tissues growing in vitro Anti-J R S from 6 rabbits, anti-J R S from 1 sheep, anti-J R.S from 1 horse, anti-human-cancer from a sheep, anti-rat-kidney from 1 rabbit, anti-rat-tissues generally from 1 rabbit, anti-rat-tissues (except kidney) from 1 rabbit, anti-M_{63} from 6 rabbits, anti-M_{63} from 9 rats Twelve rats which had been cured of two foot tumours and were thereafter immune have been "hyper immunised" by injecting into them 1 c cm. of minced J R S subcutaneously or intraperitoneally each week for 2–3 months

In all cases before beginning to make an antiserum from a heterologous animal its serum should be tested in vitro on the normal and tumour tissues of the species from which the antigen is to be taken. This is advisable, because it will be found that the sera of many rabbits, for instance, normally have a lethal effect on rat or mouse tissues and tumours When this is so an antiserum from such a rabbit will kill tumour cells in vitro, but may not do so with any great specificity

The method used in testing these sera was to culture on the same coverslip two fragments of tumour (with or without normal tissues) in separate drops of normal serum On the first, second, or third day, when growth was well established, one of these drops was replaced by antiserum and the other by an appropriate normal serum for control In this way all the conditions, except the sera to be tested, were alike

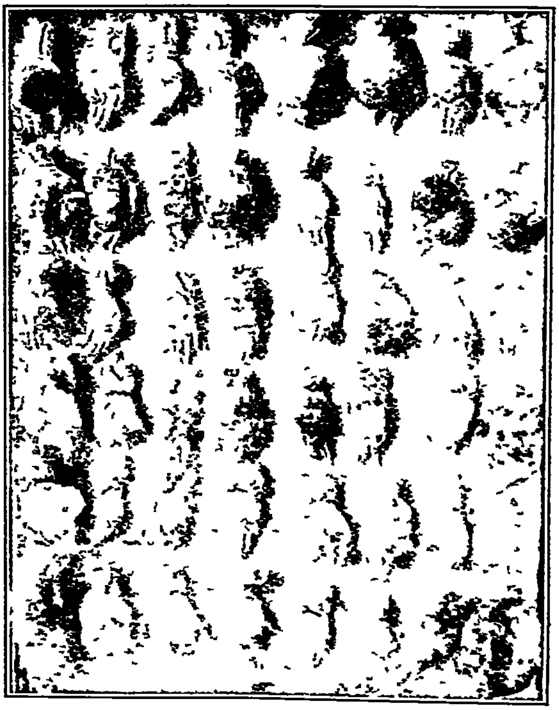
When anti-M_{63} serum from a rat is thus tested it is found to kill mouse cancer cells rapidly They never move again after the antiserum has reached them and in 10–20 minutes the other changes characteristic of chromatolytic death [3] appear [4] The normal mouse tissues (heart, kidney, salivary gland, spleen) are much less, if at all, damaged This antiserum has no lethal effect on J R S cells, in vitro, but if an anti-M_{63} serum, made from a rabbit, is applied to a culture of J R S and normal rat tissues the tumour cells are rapidly killed, while the normal tissues survive but grow less vigorously than the controls in normal rabbit serum Conversely, if an anti-J R S serum is applied to M_{63} cells and normal mouse tissues, the malignant cells die rapidly, the normal tissues survive This interchangeability of certain anti-malignant sera might mean that we are dealing with (1) anti-malignant antibodies, (2) anti-mouse-rat group immune bodies, or (3) both of these may be present Since the anti-M_{63} serum from a rat does not kill J R S cells while anti-M_{63} serum from a rabbit does, we may infer that the latter serum is lethal to sarcoma cells by virtue of the anti-rat bodies which it contains

The following results shed further light on the question —

1 *Antisera to Normal Rat Tissues* —Such antisera, if made from a wide range of rat tissues and organs, kill all normal and malignant cells of both rats and mice, but even to such sera the malignant are definitely more susceptible than the normal tissues When, however, an antiserum is made to a particular organ alone, the antibodies to the antigenic organ may attain so high a titre that if, say, anti-rat-kidney serum is applied to a culture of rat sarcoma or mouse cancer, and rat or mouse heart and kidney, the malignant cells, though they show signs of damage even more rapidly than the kidney carpet, sometimes recover while the renal cells never do so. The heart muscle cells continue to grow and show mitotic division in an appropriate dilution (1 in 4) of such a serum (Fig 2)

This special lability of the cancer cell to antibodies is all the more striking since to every other agency which has been tested by me the malignant cells (especially M_{63}) are more resistant than normal cells Thus, after growth is well established, a culture of M_{63} will survive, even if it is not re-fed, for three weeks. Under these conditions the normal tissues die after a week or ten days To ultra-violet rays,[5] radium (γ rays), bacterial infection, &c , mouse cancer cells are much more resistant than the normal tissue cells when cultured in serum

FIG 1



Photograph of specimen jar containing both hind feet of 24 control rats inoculated with Jensen's rat sarcoma Progressive tumours have developed in all save two feet The figure shows that when a virulent strain of tumour is employed spontaneous regression does not take place, except in a very few instances

2 When an anti-J R S serum from a sheep is absorbed with normal rat tissues it still proves fatal to J.R S cells in vitro The absorbed serum is non-toxic to normal rat tissues The dying sarcoma cells do not, however, in this case show all the typical signs of chromatolytic death

3 Perhaps the most specifically anti-malignant of all the sera tested is the antiserum obtained from a sheep which has been repeatedly inoculated with human mammary cancer and human breast tissue. When this is applied to mouse cancer cells cultured in vitro it kills them in exactly the same way as anti-M_{63} serum does, and almost if not quite as quickly They are dead within 5–10 minutes This human cancer antiserum is entirely non-toxic to mouse heart and kidney and even mouse skin, spleen, and salivary gland survive its application The reaction is so exceedingly specific that where cancer cells have invaded (as they frequently do) a growing carpet of normal cells they are picked out and killed instantly, while the surrounding normal

---

[4] When a culture has been killed by antiserum it may be set aside at room temperature for weeks or months without any further changes occurring in it apart from those characteristic of chromatolytic death which appeared within the first few hours after application of the antiserum. No autolytic disintegration takes place The cells appear to be fixed just as if any ordinary fixative had been made use of Whether this is due solely to the chromatolysis, or results from destruction of ferments normally present in the cells has not been ascertained This point will be further investigated It is possible that ferments may be an essential factor in living antigens I have at any rate some evidence that dead are less effective than living tumour cells as antigens

[5] Moppet The Lancet, May 1st, 1926

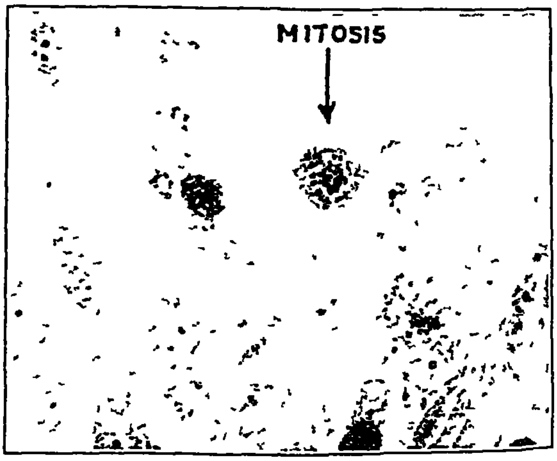
tissue cells are uninjured and continue to show mitotic division (Figs 3 and 4) The serum of this sheep tested before it was injected with human cancer was quite a satisfactory medium. Mouse cancer cells grew well in it

There has been considerable difficulty in obtaining human cancer in a condition which admits of its culture, hence it cannot at present be stated whether anti-M_{63} serum kills human cancer cells in vitro or not If it does it should contain no anti-human elements, and so should be an excellent reagent with which to attempt the treatment of cancer in man

All these rapid cytolytic effects of antisera require the presence of complement, and the addition of a little fresh normal serum reactivates certain antisera which have been kept in the cold room for over a year and which, without this addition, appeared to have lost much of their potency When no complement is supplied the antisera may still cause agglutination of the tumour cells in vitro and generally, though not invariably, the clumped cells gradually die in some 6–24 hours [6]

The point cannot yet be regarded as proved, but certain in vitro observations do suggest that cancer cells may have to a limited extent some power to acclimatise themselves to repeated applications of antisera and to other adverse conditions Although in vitro the anti-human-cancer serum would appear to be an ideal cure for mouse cancer, it does not act as such when injected into the tail vein of a cancerous mouse Large and increasing doses can be given in this way, 0 5 and later 1 c cm of the serum does not kill a 30-gr mouse When such a dose is given daily there is definite delay in the enlargement of the tumour, but if after a week the treatment is discontinued the cancer resumes its normal rate of growth. Whether more prolonged treatment will produce cure will be tried as soon as a further supply of serum can be obtained

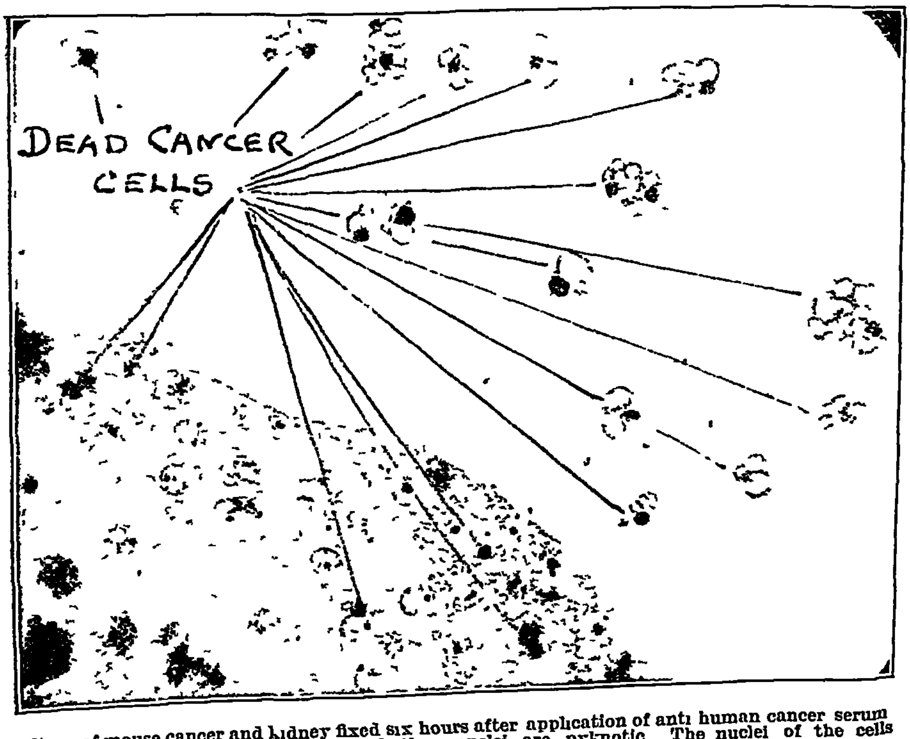
FIG 2



Carpet of rat heart muscle cells growing freely in anti rat kidney serum which had killed an adjacent culture of kidney cells in a few minutes The specimen was fixed 24 hours after application of the antiserum (× 500 Hæmatoxylin.)

The fact that a mouse which is rendered ill by a first dose of 0 5 c cm. is unaffected by twice that dose a day or two days later may indicate that the mouse has some mechanism by which it gets rid of, fixes, or neutralises the antiserum, and this may to some extent account for the disappointing result of treatment by intravenous injection It seems doubtful if the antibodies reach the living cancer cells, and if some means can be invented which will ensure this the effects of in vivo treatment should more nearly correspond with the striking in vitro results.

FIG 3



Culture of mouse cancer and kidney fixed six hours after application of anti human cancer serum The cancer cells are all dead and their nuclei are pyknotic The nuclei of the cells composing the kidney carpet stain normally (× 500 Hæmatoxylin and Sudan)

B *Production of Antibodies in Blood or Tissus of Host*

When it was observed that two coexisting tumours both regressed, although only one was treated, it appeared possible that products absorbed from the treated tumour gave rise to antibodies in the host which caused the subsequent absorption of the untreated tumour To determine whether this was so, the serum of immune and later of "hyper-immunised" rats was applied to J R S cells cultured in vitro The J R S cells, so fed continued to grow as freely as ever, even when abundance of complement was certainly present There being thus no evidence of antibodies in the serum an extract of many of the tissues of a "hyper-immunised" rat was then added to the rat's serum, but without the least damage to the cultured J.R S cells Yet the rat from which these fluids had been taken was completely resistant to J R S in any part of its body. It was clear, therefore, that there must be some fundamental difference between this "homologous" immunity of an animal to a tumour of its own species and the "heterologous" immunity evoked in a different species—e g., by injecting J.R S cells into a rabbit, sheep, or horse

---

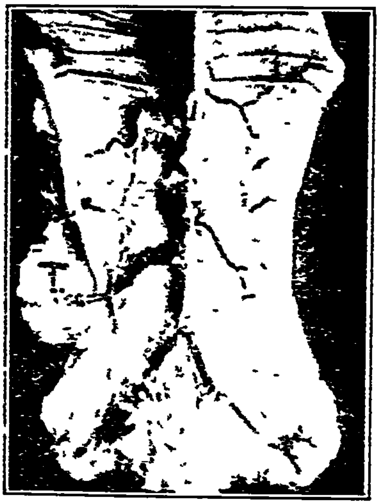
[6] The reactivation of old or heated sera by the addition of complement is not invariable Thus it was found that when a freshly prepared anti human cancer serum, which killed M_{63} cells in vitro very rapidly, was heated to 56° C for two hours, it had thereafter no deleterious effect on a culture of mouse cancer cells, and the addition of complement did not restore its activity against these cells We may conclude that in this case heating destroyed some other heat labile factor besides complement It had been noticed as the result of many previous observations that while old reactivated anti M_{63} sera were still very toxic to mouse cancer cells, they had lost much of their specificity It appears that, while mouse rat group antibodies are stable, specifically anti malignant bodies are labile to heat, and lose their activity rapidly (10–12 days) even when kept at 0° C This may explain some of the disappointing results obtained with anti cancer sera, and may have a wide application to bacterial and other antisera

To test the matter yet further, fragments of the spleen testis, or salivary gland from such hyper-immunised rats were grown in the same drop of serum with a fragment of J R S Both fragments grew as usual, the normal and malignant cells intermingling without apparent harm to either This occurred even when the fragments were grown in the serum of the hyper-immunised rat To make certain that such an occurrence could not take place in vivo J R S fragments were injected into the testes of anæsthetised "hyper-immune" rats, but (as in all other situations) no tumour resulted. Probably in such instances no stroma is supplied as was pointed out long ago by Bashford, Murray, and Cramer* and others In the case of the recovery from an untreated tumour, however, subsequent to absorption after treatment of another coexisting growth stroma must have already been present, so that possibly some other factor is involved as well as the mere refusal to form a stroma Dr. P. Bruce White kindly examined the serum of such a hyper-immunised rat by means of the precipitin reaction and also by complement-fixation tests: by neither method did he find any evidence of anti-J.R S. immune bodies in the serum.

C Possibility of a Nervous Factor in Immunity

Since no evidence indicating the nature of its immunity could be found in the blood or tissues of a "hyper-immunised" rat the possibility of its resistance being of nervous origin was considered, for a change in some nervous reactivity of the animal might explain the universal distribution of the immunity It is noteworthy that not only the veins leaving a tumour but also the arteries going to it are enlarged. Now this increase of the arteries before they have reached the tumour area strongly suggests that some nerve-reflex is at work and that it is in response to some stimulus initiated and maintained by the implanted tumour that the arteries going to the area become enlarged and possibly also that a stroma is produced (Fig 5)

FIG 5



Right Left

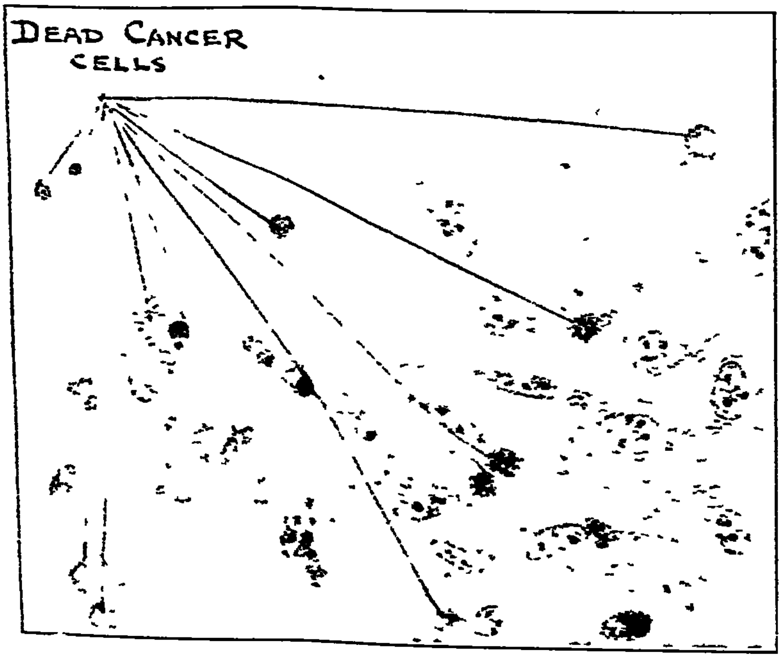
Photograph showing the enormous enlargement of the arteries on the right (tumour bearing) side The tumour (T), which formed about one-fourth of the weight of the rat has been almost entirely removed. The arteries have been injected.

In 40 rats an attempt was made to get some evidence on this point A J R. sarcoma was implanted in the sole of each hind foot of each rat and the sciatic and femoral nerves on one side were severed in some cases before, in others after the implantation. If anything the tumours grew rather more rapidly on the anæsthetised foot It would appear, then, that if any nerve impulse is effective in the way suggested above it does not pass by the ordinary somatic nerves It is impossible in so small animals to denude the arteries going to a tumour but further experiments on this question are contemplated.

Discussion.

There are two ways in which tumour antisera appear to be non-specific. (*a*) They may be non-specific to the animal from which the antigenic tumour was taken. Antiserum made in a sheep by inoculating it with human mammary carcinoma kills mouse cancer (M_{63}) cells in vitro almost instantly, while it does not kill rat or mouse normal tissues (*b*) Antisera may be non-specific to the particular antigenic tumour Any antiserum to J.R S made from a rabbit or sheep kills in vitro M_{63} almost as rapidly as J R S and, conversely, anti-M_{63} from a rabbit kills J R S cells

FIG 4



Culture of mouse cancer and heart muscle to which anti human-cancer serum has been applied. All cancer cells were killed in 10 minutes. Not a single heart cell was damaged and the heart fragment was beating actively when the specimen was fixed 24 hours after the antiserum was applied The heart cell nuclei stain normally. The cancer cells show complete chromatolysis (× 500 Hematoxylin and sudan) rapidly This may be due to the presence of anti-mouse-rat group antibodies, a supposition favoured by the facts that anti-M_{63} serum from a rat does not kill J R S cells in vitro, and that anti-rat antibodies made by inoculating a rabbit with normal rat tissues kills both J R S and M_{63} cells even more rapidly than they kill the normal tissues

---

* Third Scientific Rep Imp. Canc Res Fund, p. 355

The indication from the above observations is that when a carcinoma is injected into a heterologous animal it calls forth at least two varieties of antibodies (*a*) Anti-carcinoma antibodies, (*b*) antibodies to the group of animals from which the antigenic cancer was taken It would appear to be by means of (*a*) that anti-human cancer serum kills M_{63}, and by antibodies of type (*b*) that all rabbit antisera (made to rat or mouse tumours) kill when of high titre any variety of tumour cells from rats or mice, whether they are carcinomatous or sarcomatous Malignant cells appear to have a special lability to antibodies of almost any sort, for, as mentioned above, they are even more susceptible to a pure anti-rat serum than the antigenic rat normal tissues themselves Where, however, a single organ—e g , kidney—is used as an antigen, so high a concentration of specifically anti-kidney antibodies may be obtained that the kidney cells are even more certainly killed than the cancer cells when a diluted (1 in 3 or 1 in 4) serum is used The general impression got from application of 22 different antisera to somewhere between 400 and 500 cultures is clearly that both (*a*) and (*b*) group of antibodies are present in an antiserum made by inoculating into a heterologous animal any tumour as an antigen

The absence of antibodies in the serum and tissues of a " hyper-immunised " rat answers in the negative the second question set out at the beginning of this paper.

The mechanism of acquired immunity to a homologous tumour is still obscure, but there is reason to hold that it is not brought about by means of antibodies, such as are found in the serum of an animal into which heterologous tumour cells have been injected

The possibility that acquired immunity consists in the desensitisation of some nervous mechanism cannot entirely be ruled out, but no experimental evidence in favour of this hypothesis has been found

The negative results sometimes obtained in the treatment of flank tumours, attenuation and neurotomy do not, by any means, exhaust the possibilities, and further experiments will be made by varied methods and with different antisera

Conclusions

1 It is confirmed (50 cases) that when a rat bears a J R sarcoma on each hind foot, the cure of one by injection of antiserum is invariably followed by the regression of the other untreated tumour The results obtained when attempting to repeat this experiment with two tumours of the flank were much less satisfactory, for reasons explained above

2 A rat cured as above is absolutely immune to J R S , and test inoculations do not produce tumours, yet sarcoma cells grow freely in vitro in the serum of such a rat, even when by repeated weekly injections the animal has been " hyper-immunised "

3. If the tissues (spleen, testis, salivary gland) of such a hyper-immunised rat are cultured in the same drop of this rat's serum as a fragment of sarcoma, both normal and malignant cells flourish and intermingle without apparent harm to either There is thus no evidence that the immunity of such a rat is due to a humoral or general tissue reaction The immunity does not appear to be due to any reflex by way of the somatic nerves Attempts to obtain curative or immunising effects by inoculation of attenuated tumour cells failed, with the possible exception that fresh sarcoma cells coated with agar at 44° C may have a protective influence

4 Malignant cells were found to be more susceptible than any of the normal tissue cells to each of the antisera tested (except to anti-rat-kidney serum) The serum of many normal rabbits was found to be lethal to cancer cells, and only to a lesser degree injurious to normal mouse tissues

5 Anti-J R S serum kills M_{63} cells rapidly in vitro, and conversely anti-M_{63} serum from a rabbit kills J R S cells

6 Heterologous antisera made by injecting mouse or rat malignant cells into a rabbit or sheep contain antibodies which are anti malignant but also others which are anti-mouse-rat group These two varieties of antibodies act as adjuvants in causing the death of malignant cells in vitro

7 The rapidly cytolytic antisera require complement in order to produce their effects While addition of a little fresh serum reactivates certain sera more than one year old which had per se lost much of their potency, it does not restore their specific affinity for cancer cells The anti-malignant-cell element in antisera appears to be almost as labile as complement Anti-rat-mouse group antibodies, on the other hand, are very stable

8 An antiserum made to rat kidney alone is more toxic in vitro to rat kidney than to any other tissue on which it was tested

9 An antiserum made by inoculating human mammary cancer into a sheep kills M_{63} cells in vitro practically instantaneously It is non-toxic to mouse heart or kidney, and has little, if any, deleterious effect on mouse salivary gland or skin This serum damages J R S cells but not normal rat tissues in vitro

10 This anti-human cancer serum can be injected intravenously into mice in massive doses—e g , one-fiftieth of the body-weight—without serious damage At second and subsequent inoculations mice can tolerate twice this dose

My grateful thanks are due to Prof C J Martin, F R S , for allowing me the privilege of working at the Lister Institute and for his advice and encouragement I am also much indebted to Miss A C Kohn-Speyer, B A , a voluntary worker, for her skilful help She has recently done most of the practical work involved in the tissue culture experiments Specimens of human cancer have kindly been supplied to me by the Middlesex Hospital surgical staff through the good offices of Prof S Russ, by Sir Crisp English, K C B , Mr G H Fagge, Mr W H Ogilvie, and Mr Max Page Mr Sampson Handley has kindly sent me specimens from private as well as hospital cases Finally, I must express my gratitude to the British Empire Cancer Campaign, whose grant has made it possible for me to devote my whole time to cancer research The Campaign has also most cordially assisted me in every other way in its power

Note —Since the above was written, the serum of a rabbit which had for another purpose been inoculated by a colleague repeatedly with the spermatozoa of a higher mammal, has been tested upon mouse cancer cells and normal tissues The antiserum kills mouse cancer cells typically and rapidly, it is less deleterious to mouse kidney, and does not damage fibroblasts or heart muscle cells This observation opens up a wide field for future investigation It appears to indicate that cancer cells are specifically labile to antisera made against certain heterologous toti-potential cells It is proposed to try whether an antiserum made against normal mycetozoal cells would act in the above way and also whether by inoculating a cancerous animal with some such primitive cellular antigen or with some heterologous cancer, it could be made to produce antibodies which would incidentally destroy the cancer cells growing in it

PSYCHIC TRAUMAS

(MENTAL ACCIDENTS*)

BY ALBERT E DAVIS, F R C S EDIN, L R C P,
HON PHYSICIAN, LIVERPOOL PSYCHOTHERAPEUTIC CLINIC

THE public, the medical profession, and many psychologists are apt to look upon every strange mode of thinking, such as phobias, obsessions, &c, as abnormal, and the word abnormal has come to be regarded as synonymous with diseased. We have been forced to take heredity and environment into our calculations, but have we up to the present taken chance or accidental causation into consideration sufficiently? I maintain we have not. We have gone far afield, and have dug very deeply, down to the infantile and the prenatal, in our psychological explorations, whilst in many cases overlooking the obvious. In dealing with physical ailments this attitude does not obtain, we are ready to consider either accidental or pathological causation, and this paper is a plea for the adoption of a similar attitude in psychical dysfunction.

Why should we assume that a woman found wandering in a strange town at 3 A.M. with total loss of memory is mentally afflicted? May it not be that, owing to the conduct of a drunken, blackguardly husband her conscious mind has been strained beyond endurance and has passed into a state of recuperative oblivion? I had such a case recently.

Are tired and exhausted brain cells to be looked upon as diseased? If so, let us be consistent and classify tired muscles as diseased. The pronounced difference in the reaction of muscles to fatigue from the reactions of mind and nerve may to a great extent account for our general attitude. Tired muscles refuse to work until they are rested, tired minds and nerves, on the contrary, become distressingly active and hypersensitive until absolute exhaustion ends in trance or oblivion.

The peevishness and irritability of a tired child finds its counterpart in the peevishness and irritability of the nervously exhausted adult—the neurasthenic. During the late war the long-continued strain of unaccustomed, disagreeable, and frequently intolerable conditions of life in the trenches, together with repeated mental shocks in soldiers of sensitive temperament, caused in some instances a complete cessation of mental activity. They were found wandering aimlessly around without memory, knowledge, or thought. Exhausted nature had blotted out consciousness to give it rest. This is the sleep of utter exhaustion, and is a temporary condition which ought not to be confused with actual degeneration of the brain due to disease. The causes are accidental, not pathological. It may be claimed that such cases occur only in persons of unstable, nervous constitutions. I contest this. It may occur in healthy, highly sensitive nervous organisations.

Again, I can conceive of circumstances which would break down the power of resistance of any human being. I do not claim that trauma is the only cause, but I do claim that it is a frequent cause, and ought to be borne in mind when we are searching for the causes of phobias, obsessions, and alterations in conduct and thinking. I take measures to exclude accidental mental stresses before I assume disease, and the percentage of cases which one can trace to accidental circumstances is astonishing.

The therapeutic value of this attitude is frequently very marked. The encouraging effect on the patient of learning that his symptoms have resulted from accidental circumstances and not from mental defect is in itself sufficient to warrant the psychotherapist adopting this as a routine method. Cases of somnambulism or ambulatory automatism are due according to Prof Pierre Janet, to a dissociation of personality. He attributes this dissociation or splitting of the personality to a lowering of nervous tension, with exhaustion of the higher functions of the brain and a consequent retraction of the field of consciousness. The lowering of the tension may have been due to mental stress or emotional shock. I am in agreement with Janet on this part of his theory, but I join issue with him when he regards every dissociation, whether spontaneous or not, as evidence of hysteria.

Criticism of Freud's Determinism

Prof Sigmund Freud says the determining factor of dissociated memories is mental conflict brought about by incompatible desires, such as a wish which is unbearable or distasteful to the rest of the personality. The desire is too painful or obnoxious to be entertained in consciousness, and it is persistently repressed and pushed out of consciousness, so becoming dissociated or split off from the personality. He claims that such wishes invariably can be traced back to early or infantile sexualism. Now the object of my paper is to draw attention to the importance of chance or accidental circumstances in the production of phobias, obsessions, dissociations, and perhaps minor forms of delusions.

By chance I mean only such accidental circumstances as have given rise to intense mental emotion or stress. Right on the threshold I find myself opposed by Freud. He allows little or nothing for chance. His theory is one of rigid determinism. He and I are in agreement that in the mental sphere there is no effect without a cause. But there we separate. I maintain that emotion originated by external factors of sufficient intensity can produce a splitting off of a part of the personality, a part which pursues its own course independently of awareness and of the will. A chance occurrence to him is simply a convenient point round which we get the conflict between infantile sexual desires and the conscious Ego or personality. In order to support his theory that our thoughts, our reactions to circumstances, have been so rigidly determined for us beforehand that we are never free agents, he has dug down to the level of primitive instincts, and held up the infantile sexual as the determining force for the whole of our lives.

I also propose to dig down into the primitive and see if I cannot disclose a yet stronger instinct round which the play of feeling will account for dissociation without the necessity of accepting Freud's determinism. Whilst differing from Freud's theory of ultimate causation, I have the greatest admiration for his original and practical methods of unearthing hidden mental processes.

He approached the psyche from the aspect of disease, hysteria, and found by association of ideas that his mental analyses frequently led him into the childhood of the patient. At this earlier period of his work he had a more open mind, and he searched for traumas in the childhood age. He found that in several of his cases gross sexual bodily outrages had been inflicted on them, and that in others the outrages had been the witnessing of scenes so improper, or environment so sexual, as to inflict a permanent injury upon the child's future mental and moral outlook.

I have had many similar cases. Freud, speaking of this period of his work, says of himself and his colleague, J. Breuer, "We reached the conception that the hysterical symptoms are permanent results of psychic traumas, and that the amount of affect (feeling) belonging to them was pushed away from conscious elaboration by special determinations, thus forcing an abnormal road into bodily innervation."[1] He starts off with the theory of psychic trauma, but then experiences a check, he finds that many of these tales of seduction or outrage were simply hysterical fancies, and later still he finds these fancies had a purpose—they were to conceal early sexual perversion in the patient himself. He made hasty and too far-reaching conclusions from a mere handful of very morbid material. "My 13 cases of hysteria were throughout of the graver kind, they were all of long duration, and some of them had undergone a lengthy and unsuccessful asylum treatment."[2]

---

* A paper read before the Liverpool Psychological Society.

Freud, still approaching the subject by the morbid route, with an unconscious bias urging him to make the exception into the rule, surrounded by an atmosphere of hysterical (or insane) deception and, limiting himself to the study of hysteria, found his progress barred by this complication.

The "Traumatic" Element

He says: "The emphasis laid on the 'traumatic' element of the infantile sexual experience disappeared with this explanation, and it remained obvious that the infantile sexual activities (be they spontaneous or provoked) dictate the course of the later sexual life after maturity."[3] Personally, I fail to see anything obvious except his own obvious bias towards one single idea to cover the whole field of psychical disturbance. He will give up the traumatic theory, but holds on grimly to the sexual, and to support his theory digs deeply into the infantile and even into prenatal life.

But he is now faced by another difficulty. All infants are very much alike, and if some have, they all have, sexual wishes, so he builds up elaborate theories of a pleasure principle and a reality principle dating from or soon after the birth of the child, and going on in the unconscious and preconscious minds independently of consciousness. By the interactions of these principles the sexual tendencies of the infant may be sublimated, or refined later on into channels of useful and socially acceptable activities; this is the normal result. If these primitive wishes are not repressed they persist in adult life as sexual perversions. If they are repressed too much we get prudery and extreme bashfulness. If the strengths of the sexual wish and of the repression are about equal we get a nervous complaint. Freud maintains up to the present, "In a normal vita sexualis no neurosis is possible."[4] Some cases of neurosis undoubtedly have had an abnormal vita sexualis, but to make this theory universal is proof that the author is suffering from an unconscious sexual complex. He has become such a rigid determinist that he lays down the general law that nothing happening to a child after the age of 5 can cause a psychoneurosis in later life.[5]

If Freud had said, "In neurosis we may find an abnormal vita sexualis" I would have agreed with this, and there would have been no necessity for my bringing his theories into discussion. But when a scientist of his weight and position says, "In a normal vita sexualis no neurosis is possible," and he publicly discards the traumatic theory, it leaves me no other course than to challenge the correctness of his assertions if I am to obtain a hearing for my contention that accident plays a greater part in the production of neuroses than infantile sexual tendencies. In order to find an originating cause for neuroses Freud delved into the primitive and found one in the sexual instinct.

The Most Powerful Primitive Instinct

I propose to delve down there to ascertain if there is not another instinct there, complementary to Freud's, as a cause of neurosis and I find the instinct of self-preservation to be of greater moment and of greater intensity than that of reproduction. Without it the great part of animal life would become extinct. The "sine qua non" of the instinct of self-preservation is the instinct of fear.

If there were no fear—if man had no fear of the tiger, the rabbit no fear of the dog, the sparrow no fear of the cat, the animal world in time would consist solely of the carnivora, and the carnivora would walk into the sea and get drowned. Fear is a biological necessity which Freud appears to have overlooked.

How does an animal react to danger, or fear? In one of three ways—flight, fight, or fright. All of these reactions are mainly in the instinctive and emotional level. It may be through conscious perception that fear is roused, but once aroused, conscious thought and reason take a secondary place in the reactions. The sympathetic nervous system, which is intimately associated with emotion, assumes control. In the case of flight, through the action of the sympathetic, the animal's limbs are flushed with blood, and the whole of its potential energy is focused and directed to speed. The hunted hare has only one motive—to run as it never in its life ran before. I think it must be admitted that nervous fear of company may cause blushing in a young girl without inferring sexual wishes and repressions in her infantile and unconscious life. If flight is checked or is impossible the animal may seek safety in fight; a cornered rat will turn and fight man or cat. A man, if he cannot escape by flight, may turn and fight with the fury of a Berserker. In the remaining reaction, fright, the object is to escape by concealment. The rabbit crouches down trusting the dogs will overlook him; theirs is an actual paralysis of motion and of will. We find everyday expressions indicating a similar condition in humans: "He was paralysed by fear," "struck dumb by terror," "fear rooted him to the spot," &c.

Fear the Most Frequent Cause of Neurosis

I here make an emphatic declaration. The instinct of fear is the most frequent cause of neurosis, and the sexual instinct is a much less frequent cause.

Now let us return to the case I referred to earlier. This poor woman was subjected to repeated emotional stresses due to a drunken husband, continually on the alert for danger, strained beyond endurance, when a merciful provision of Nature blotted out her pain by unconsciousness, and the primary law of self-preservation drove her onwards in blind, instinctive flight. I decline to admit Janet's theory of hysteria or Freud's theory of infantile sexualism in this case. When we contemplate the terrible strain of life in the trenches during the late war, it is marvellous that so few men broke down and, obeying the law of Nature, found refuge in unconscious and instinctive flight.

Some psychologists would have us assume that the determinants of action are to be found in the subconscious, or in the unconscious. If so, what part does conscious reason play? Man without reasoned control is a child, or is insane. The prime function of reason is to restrict feeling, imagination, desire, conduct, within moderate limits. Reason can be partially or temporarily displaced by an overwhelming wave of emotion due to external factors, and if these are of sufficient intensity no inherent nor abnormal tendencies are necessary.

I endeavour to approach my cases from the standpoint of the normal, and in any departure from this I endeavour to keep an open mind as to causation—hereditary, constitutional, acquired disease, environmental, hysteria, sexual or traumatic. A good physician makes the diagnosis fit the patient, and not the patient fit the diagnosis.

Illustrative Cases

The following cases will, I think, bear out the views I have expressed:—

CASE 1.—A lady consulted me suffering from claustrophobia (dread of enclosed places) as one of her chief symptoms. The cause of claustrophobia is most frequently the dread of being taken suddenly ill and not being able to quickly get out of the train, church, or crowd, as the case may be. This second dread is frequently due to a third phobia, the fear of heart disease, and this is the phobia that has to be traced and treated. I put this before the patient, and to my surprise she denied any fear of heart trouble; she was afraid of actual vomiting. At 6 years of age she had been terrified by seeing a lady vomiting in church, she had nightmares of this, and refused to go again to church until forced to do so. The impression partly wore away, but never quite disappeared. At 10 years of age she was crushed in a circus crowd; this aroused a fear of suffocation and death. At 12 years of age she found herself in a crowd in a railway station; she experienced the same sensations and afterwards was unable to travel in a train or cab unless accompanied by a companion, and even then she suffered great mental distress. The symptoms were disproportionate to the alleged cause, and her mother supplied the missing clue. At 2 years of age she was suffocating with (?) whooping-cough, when her mother rushed to her and putting her finger down the child's throat pulled out a piece of flesh. Evidently this must have been diphtheritic membrane. The patient could then recall her feelings at the time, and they were similar to her later ones.

The relief of mind by bringing the repressed memories up into consciousness and quietly discussing them was immediate and marked The same day she sent her husband on to a café to wait there for her whilst she made a call, the first time in her married life of 12 years that she had offered to walk alone in the street. Within a few days she was travelling long distances alone in a taxi-cab

On her next interview she asked me if a certain widely-advertised remedy would cause heart disease if taken in excess, and confessed for the first time that prior to her marriage she had drunk a bottle of this preparation in one day, and hearing a day or two afterwards that a man had died from heart failure due to an overdose of this remedy, she had ever since had a secret fear of her heart being diseased This is interesting in view of her previous denial She had suppressed it from her people, had denied it to me, and had tried to repress it from her own consciousness, probably from a feeling of shame—a clear example of a mental conflict which was not sexual I showed her an analysis of this preparation—it was simply citric acid She was cured of all her phobias and has remained so

Freudians would claim such a case as a psychoneurosis due to sexual wishes being repressed in infantile life I am convinced she had a normal vita sexualis

CASE 2 —A young man consulted me for a rather unusual phobia His work necessitated him visiting in his neighbourhood and he was seriously hampered by an unreasoned terror of a certain 300 or 400 yards of the main road He indicated the exact spots where the panic started and where it ceased, and in order to avoid this he made wide detours In addition he had agoraphobia (dread of open spaces) This part of the road had no painful associations Did it differ materially from the rest of the road ? Yes it had walls and hedges on both sides and no shops nor houses This gave the clue He could not pass down any street with blank walls on both sides he was in terror of being alone and of falling or collapsing with no one looking out of windows or doors to see him fall

He gave the history of a discharging ear from 14 years of age. From 15 to 18 he could not walk steadily , he had to have people on both sides of him Evidently he had had middle-ear disease affecting the organs of balance, the semicircular canals At 30 years of age he was frequently falling , a right mastoid operation was then performed with success, restoring his perfect balance

The originating phobia had been a natural protective instinct to keep him out of danger It had persisted in the subconscious in the form of a habit for four years after its necessity had ceased By exercises and tests I satisfied him that he was definitely cured of his former instability and giddiness, and in a short time he freed himself from his phobias

Freudians say of a phobia " It symbolises certain unconscious wishes—ultimately wishes derived from the period of infantile sexuality—and makes manifest the fear with which such wishes would be regarded by the moral self of the patient if they became conscious "[6] The cause in this case is so obvious that I do not propose even to discuss an infantile sexual origin I have known such persistence of fear follow injuries to joints and such cases may account for some of the successes of bone-setters

CASE 3 —An interesting case was that of an old man who had a most distressing phobia of the slightest draught or current of air If he passed an open shed on the dock road and felt the least wind he became ill and was compelled to go home to bed If anyone passed him in a room it caused him to have hot flushes and " creepy tinglings " down his legs He had suffered from this for 17 months his people had lost patience with him, and he came to ask me if he was becoming insane

I obtained the following history One night on arriving home his people were out , he made himself a meal and then fell asleep in front of the fire Influenza was raging at the time and he was afraid of it He was awakened by a shivering fit and thought he had caught it During the following week he had three more shivering fits in the night time, and from then suffered from the phobia described A little further inquiry elicited the cause of the first rigor a cause he had never taken into account It was a cold night and the fire had gone out ! We must not look upon this as foolish that would be a hasty and superficial attitude. The old man was not fully awake when panic seized him and panic displaces reason

I did not spend months or years unearthing or imagining an infantile sexual conflict in this case—as a matter of fact I never mentioned sex to him I treated him by quiet discussion on 11 occasions, with light hypnosis to calm his nervous system, and he made a complete recovery On his later visits he vigorously fanned himself with a newspaper to reaccustom himself to draughts

CASE 4 —A lady was sent to me from an eye and ear infirmary as suffering from functional giddiness No organic disease was discoverable The fear of falling was so persistent she was afraid to go out alone. She improved under suggestion, but rather slowly, so I resorted to mental analysis Using Jung's word association tests I found an intense fear of water Water such as a park lake fascinated her, although she was horribly afraid of it She had no suicidal tendencies She strenuously denied being worried over some near friend or relative having to go to sea The reactions indicating this were very marked, and on my insisting she ultimately admitted that her husband frequently had to cross to Ireland, and on these occasions she sat up all night and could not sleep Her previous denial was an attempt to suppress an unbearable thought from her field of consciousness and to avoid discussing it with me

I obtained the following history from her, which she had apparently forgotten, and which she had never told her husband nor friends Suppression again, due probably to the painful nature of the memories At 10 years of age she was sent to live with her grandmother She was very unhappy there, so much so she told her parents she would drown herself in the well if they did not take her away She distinctly remembers really meaning to do so

At 17 years of age she was sitting on a camp stool on the beach at a seaside resort A passenger steamer, instead of slacking speed, came in at full speed and collided with the pier A huge wave from the backwash of the steamer surged up the beach The other people at the edge of the water ran for safety but she was paralysed with fright, and the wave washed her out into deep water She was only rescued from drowning at the last moment

The unearthing of these painful suppressed memories was immediately followed by a disappearance of all her symptoms I never broached the sexual question

CASE 5 —An engineer's labourer consulted me for rigidity of his spine He was unable to bend forwards and could not climb stairs owing to " tightness " of his legs He suffered very little pain On examination there was no marked tenderness of the spine, rotation was normal, flexion very much restricted Knee-jerks increased, no incoördination. Evidently a case of hysterical spine

The history was as follows Eight years previously an iron plate weighing 14 tons was swinging from a crane when the chain broke and the plate falling on his right arm crushed it, disabling him for six months At the end of that period he returned to light work, and for 7½ years he had been on light work through inability to bend his spine He was not malingering , there was no question of lawsuits or compensation in the matter He had been a saving man He had travelled a good distance stayed in Liverpool eight weeks, and paid my fees out of his own pocket in his anxiety to be cured

His back had not been injured and he was not shamming ; what, then was the most likely cause of his disablement ? Elsewhere[7] I have quoted several similar cases in which the cause proved to be suppressed fear It was the same with this patient , the cause was fear kept up by the instinct of self-preservation Some part of his mind outside the region of conscious awareness had formulated the idea that if he could not bend his back he would not again be exposed to such a danger It was a purely instinctive protective reaction Some confirmatory evidence of this is that bending was alone affected rotation of his spine and twisting of his body was normal Rigidity of the spine was merely a symptom, and to treat the symptom only by suggestion or any other method, would have been useless, as the originating fear would have found expression in some other symptom

The radical cure was to explain the cause to the patient to point out the intensity of the fear, and the advisability of removing the fear by ceasing to work under such risks in a shipbuilding yard He saw the logic of this advice and said he would take a proffered partnership in a motor business The result was most satisfactory , in a few weeks he could lace his boots, bend and lift weights quite normally, and was fit for full work under less risky conditions

Freudians would call this a psychoneurosis, a conversion hysteria Mitchell says—

" We have seen how, as a result of deprivation and regression of the libido earlier erotic activities of childhood are revived, by way of unconscious phantasies and come into conflict with the ego tendencies of the patient As a result of this conflict a compromise is effected and the repressing forces, as well as the unconscious wish pertaining to the phantasy, achieve some sort of satisfaction in the hysterical symptom which emerges The symptom is not, indeed, recognised by the patient as any form of satisfaction but rather as suffering and it is through the latter quality that the repressing forces are gratified—the symptom is an expression of the disapproval with which the personality meets the re-awakened infantile wishes."[8]

My object is not to criticise Freud's theories except where they clash with mine I leave the reader to judge which of the two theories comes nearer to the truth in this case

Summary.

In conclusion, as against Freud's dogmatic determinism, I advance my theories as to the causation of the great majority of neuroses 1 The unbearable idea or wish arises in consciousness and not in the unconscious nor in the infantile sexual 2 The unbearable idea is not repressed into the unconscious by an intra-psychic censor It is deliberately suppressed by conscious effort into the subconscious—into present unawareness—not deeper 3 When the complex is laid bare it is evident that the patient must have been aware of it at some period, if not throughout 4 The causes are therefore to be sought for in adult life, or in youth, rarely in childhood, and only exceptionally if ever, in infantile sexuality 5 The majority of neuroses are founded on moral or physical fear 6 The fear may be an instinctive protective reaction 7 The fears are frequently due to external causes (chance) and may be described as psychic traumas or mental accidents

TORSION OF THE GALL-BLADDER

By G P B HUDDY, M S Lond F R C S Eng,
SURGEON, DUDLEY ROAD HOSPITAL, BIRMINGHAM

Torsion of the gall-bladder is a rare condition Irwin[1] in recording a case in the *British Journal of Surgery* in 1921 stated that as far as he could trace, his was the eighth recorded example In 1922 in the same journal Lett[2] drew attention to a case which he had recorded in The Lancet in 1909[3] and which had been overlooked Since Irwin's case others have been recorded by Frankau,[4] Jonas,[5] and Fifield[6] The following would appear to be the thirteenth case The fact that five have been recorded in comparatively recent years suggests that the rarity of the condition has been exaggerated

There are two important factors which predispose to torsion of the gall-bladder

1 *The Presence of a Mesentery*—This of itself is sufficient to permit of torsion of the gall-bladder, as in the case recorded by Frankau, in which the torsion had occurred on a mesentery which had a narrow gall-bladder attachment

2 *The Length of the Cystic Duct*—According to Brewer[7] the cystic duct varies in length from ½ to 2½ inches and Walton[8] states that it is normally about 1½ inches long If there is a long cystic duct together with a mesentery the gall-bladder may hang almost free from the liver edge Such a combination of factors increases the liability to torsion In the example recorded by Wendel[9] the duct was 3¼ inches in length

Report of Case

A woman aged 71, was admitted on Dec 30th, 1925, with an illness of 50 hours' duration The onset was sudden While sitting down she felt very ill and faint this was followed one hour later by the onset of pain which commenced in the epigastrium and radiated to the right abdomen, where it settled It was severe in character and "went through to the back" There had been no vomiting The bowels were open and there were no urinary symptoms

No history was elicited of any previous attacks of the same kind, but for 17 years she had suffered from "bilious attacks" which came on at monthly intervals and consisted of pain, beginning an hour after food, rising into the chest, and relieved by vomiting There was also a history of flatulence

On examination the temperature was 98° F and the pulse-rate 108 There was marked tenderness and rigidity of the right abdomen at the umbilical level A few days later a definite rounded lump was palpable at this same site, the swelling being dull on percussion and not appearing to move on respiration

With the history of epigastric pain radiating to the right abdomen and the presence of a swelling, a diagnosis of appendix abscess was made and, since the "abscess" was not resolving operation was decided upon, although the patient was old and her general condition poor

Operation was performed under general anæsthesia The abdomen was opened through a vertical incision and the rectus muscle was not retracted There was a well-shut-off lymph covered cavity containing a rounded swelling which proved to be a gall-bladder that had made one turn on its neck in an anti-clockwise direction The gall-bladder was removed with great ease as there was a narrow mesentery in the region of the neck and the gall-bladder was hanging from the liver edge As there was no raw area on the liver the abdomen was closed without drainage On examination the gall-bladder was congested but there were no stones The wound healed soundly

The case illustrates the main features of this rare condition—viz . (1) The failure of pre-operative diagnosis (2) The sex—all females (3) The condition arises particularly in people of advanced years, the two exceptions being those patients, aged 23 and 34 respectively, seen by Wendel and Irwin (4) The sudden onset (5) There is always a history of right-sided pain This may be associated with epigastric or general abdominal pain, as in the above case and those of Irwin, Frankau and Jonas Occasionally the pain may radiate to the back. (6) A swelling, either rounded or sausage-shaped, is usually present but in the early stages it may be masked by rigidity as in my case or it may be hidden by the liver Frankau s case affords such an example Whether it is mobile or not depends upon the extent of the adhesions A very interesting example is afforded by Wendel's case in whom in November, 1895, a cystic swelling was discovered which varied in position, and which in October, 1896, was found to be fixed (7) The operation is usually an easy one on account of the mobility of the gall-bladder and the length of the cystic duct, and so the prognosis is good except in so far as the patients are elderly (8) There may be a previous history of "bilious attacks" (9) Associated abnormalities may be present Wendel recorded a floating kidney, and in my case there were cysts in the liver An atypical feature of my case is the absence of vomiting, which is usually frequent or even incessant

St Bartholomew's Hospital War Memorial—On July 8th the Prince of Wales unveiled the memorial to students of St Bartholomew's Hospital who fell during the war It takes the form of a new arched court leading from the Henry VIII gateway to the hospital square There are four panels bearing the names of 113 students, and around the court runs the inscription, "These gave their lives for King and Country, counting not the cost in defence of right" The Army, Navy, and Air Force Medical Services were represented at the ceremony by their directors and the City of London by the Lord Mayor and Sheriffs A short service was conducted by the Chaplain-General to the Forces, Dr A C E Jarvis, and a volume containing the names recorded in the memorial was presented to the Prince by Sir Anthony Bowlby

Clinical and Laboratory Notes.

SOME CASES OF LONG-STANDING DRUG ADDICTION

By STANFORD PARK, M.B , CH.B EDIN ,
RESIDENT MEDICAL SUPERINTENDENT BAY MOUNT, PAIGNTON, HOME FOR ALCOHOLISM, DRUG HABITS, AND NEURASTHENIA.

PHYSICIANS specialising in the treatment of drug cases felt considerable apprehension after the passing of the Dangerous Drugs Act, when elderly drug addicts of many years' standing began to seek their advise and present themselves for treatment Many of these patients were pathetic objects and when, eventually, their treatment was undertaken, it was always with the expectation of an anxious time

On one occasion a patient, aged 71, with an addiction of 30 gr of morphine daily for 40 years, presented himself for treatment He had put his affairs in order, had made his will, firmly expected to die under treatment and " leave his bones amongst us," as he expressed it, whereas, in reality, he left here after a few months to get married ! This is a specimen case, but consideration of a series of these cases demonstrates that these chronic subjects can be cured with less trouble and suffering than patients of half their age and with only a few years of addiction The cases also prove—a fact not always recognised—that a man can carry on his life's work and at the same time take considerable doses of morphine What is more remarkable still they prove that a man may hide his failing from his nearest relations and friends—even his wife

The three examples which follow are typical of the elderly cases which the Dangerous Drugs Act has caused to come for treatment

CASE 1 —This was a professional man, 65 years of age. In his younger days he had achieved some degree of success, and all his life he had been a keen sportsman, fond of shooting fishing, and hunting He had first taken morphine 35 years before to relieve the pain of a hunting injury, and except for a few periods after treatment he had continued the habit taking from 5 to 20 gr at various periods On admission he was taking from 8 to 10 gr daily He had also taken alcohol to excess off and on all his life When this patient arrived for treatment he had been without his drug for 20 hours and was in a state of collapse He was put on a graduated dose of morphine and soon recovered from the collapse He then underwent the usual course of treatment His appetite was poor and he felt the characteristic withdrawal weakness considerably, but he only stayed in bed two whole days at the time of complete withdrawal He had chronic bronchitis and this and the cough and expectoration bothered him at night

He soon began to recover and within a fortnight of withdrawal he went with his male nurse eight miles by car and fished in the River Dart for several hours When he left he was active and cheerful and looked quite ten years younger than on admission

CASE 2 —A retired clergyman, aged 74 years, who had been taking morphine continuously for over 40 years It had been given to him first for neuritis in his feet, and he had continued to take it without any intermission He had carried on his work as a clergyman all this time and had been rector of his parish for many years Neither his wife nor anyone else had had the slightest suspicion of his habit His average daily dose appeared to be about 7 gr The patient was practically an abstainer and the question of alcohol did not enter into the case This patient preferred to stay in his room generally in bed during the withdrawal period, and he complained very little of anything and showed no marked symptoms until at the point of complete withdrawal he complained of pains in his feet and he said they were the same kind of pains as those for which he had been given morphine 40 years previously Various remedies were tried and after about a week the pains subsided and did not return This patient suffered a good deal from nasal catarrh but otherwise was remarkably well He gradually regained strength and at the end of 12 weeks was driving his car

CASE 3 —This was a professional man 71 years of age and still carrying on his profession who had taken morphine for 40 years He first took it to try its effects after observing the comfort it gave to one of his patients He had taken it without any break for over 40 years His average daily dose was 30 gr , taken in two doses of about 15 gr each, morning and evening In addition to this since the death of his wife some years ago, he had taken a bottle of whisky daily In this case also neither his wife nor his friends suspected the habit On admission he was in fairly good health, but his blood pressure was 220, and his pulse at times intermittent He also had a large umbilical hernia caused by straining due to constipation. As is my practice in cases of double addiction the alcohol was first of all reduced and gradually discontinued and then the morphine was also gradually reduced to 2 gr daily without any unpleasant symptoms Then one morning, about 1 A.M., he had a heart attack and his pulse became very irregular and fluttering, and he was very nervous and frightened But after an injection of morphine his heart calmed down and he was asleep in 20 minutes and had no return of the cardiac irregularity during his stay. At the actual withdrawal stage he felt disinclined for exertion and stayed in bed for three days, but he had no withdrawal symptoms except the feeling of weakness and some burning sensations in his intestines Five days after withdrawal he was told he had not had any morphine for five days, and from then onwards he progressed steadily and showed much mental exaltation and lightness of spirits He delighted in his " freedom from bondage," as he expressed it, and was most grateful to everyone concerned. He left here after a 12-weeks' stay and he looked and said he felt 15 years younger than when he came His blood pressure had fallen to 180 and his heart gave him no trouble He has since written me that he has continued to get stronger and the last news of him was that he had married again

Compared with younger patients, these old men did remarkably well, and their suffering was slight

There is another aspect of this question which may not have received sufficient consideration from the authorities, if it has had any at all. and that is the effect of treatment on these old patients' moral and emotional natures After a man has lived in an artificial world of his own making for 30 or 40 years, with all his senses dulled, there are bound to be unexpected and even undesirable manifestations when at last he emerges from his tomb and his whole nervous system is alert and hypersensitive to every impression and stimulus The conduct of all three of these patients was such as to give grounds for anxiety for they might easily be involved in legal proceedings

OBSERVATIONS ON A CASE OF ACHOLURIC ICTERUS

By GEOFFREY HADFIELD M D , M R C P LOND ,
AND
T F. HEWER
(*From the Pathological Department General Hospital, Bristol*)

Prof Barcroft's address on the functions of the spleen, published in a recent number of THE LANCET, prompts us to submit the following account of a case of acholuric icterus in which the blood of the splenic vein was examined immediately after splenectomy

The patient, a man of 29, was known to have an enlarged spleen at the age of 12 When seen at the age of 26 the spleen reached to the level of the umbilicus he was jaundiced but bile pigment was absent from the urine The blood showed a leucocytosis of 18,800, accounted for by an absolute increase in lymphocytes There was an excess of urobilin in the urine and of bilirubin in the blood plasma Since then he has been troubled with epigastric pain and considerable drowsiness and states that his jaundice, though liable to considerable fluctuation in intensity, is increasing slightly No family history of jaundice or splenomegaly was obtained. An examination made a few days before splenectomy showed —Blood Red cells, 4 352,000 per c mm. Hæmoglobin, 75 per cent. , C I , 0 86 White cells, 19,700 , increase due to lymphocytosis Moderate micro-anisocytosis and slight polychromatophilia of red cells Blood fragility. Maximum resistance, 0 6 per cent , minimum resistance, 0 44 per cent. Van den Bergh reaction Positive, indirect ½ unit Blood spectrum normal. No serum auto agglutinins found Lævulose tolerance test normal Urine moderate excess of urobilin, no unaltered bile pigment After splenectomy the blood aspirated from the splenic vein showed maximum resistance 0 75 per cent minimum resistance 0 45 per cent Van den Bergh reaction positive, indirect, 2 units.

The spleen weighed 1 lb 7 oz, was 7¾ in in length, and histologically showed the usual reticulo-endothelial proliferation, engorged sinuses, and red cell phagocytosis

Orahovats has demonstrated that, in a normal animal, the red cells of the blood in the spleen pulp are more vulnerable to the lytic action of hypotonic saline and less vulnerable to that of saponin than are the red cells in the general circulation This result was obtained in the blood leaving by the vein after ligature of the splenic artery and stimulation of the splenic nerve By this manœuvre red cells were obtained direct from the spleen pulp, cells merely passing through the organ and escaping, its "filter-bed" being eliminated Prof Barcroft inclines to the view that this increased fragility is not acquired during the sojourn of the cells in the spleen pulp, but that cells which are fragile from some unknown physiological cause are retained by the spleen acting as a differential filter

In the case we report, the cells of the blood aspirated from the splenic vein were more fragile than the abnormally fragile cells of the general circulation It is not unlikely that the blood we obtained came from the spleen pulp, for ligature of the pedicle would probably be sufficient stimulus to the splenic nerve, and the delay between ligature and removal would allow sufficient time, for the splenic sinuses to deplete themselves It is obvious that such a result as we obtained in a diseased organ might very easily have been misconstrued if the fundamental physiological facts regarding normal fragility had not been available

---

ACUTE INTUSSUSCEPTION IN AN ADULT

By F W WIDGERY, F R C S ENG,
SENIOR RESIDENT MEDICAL OFFICER, BRISTOL GENERAL HOSPITAL

THE case below is thought worthy of record because of the unusual occurrence of the acute condition in the adult Furthermore, it illustrates the extraordinary power possessed by some individuals of recovery from the moribund state

Mrs D, aged 43, was admitted to the Bristol General Hospital at 10 30 P M on March 13th, 1926, with a history of four days' severe and continuous abdominal pain and vomiting, of sudden onset Her previous history was of no account

The condition on admission was as follows Her expression was anxious, she vomited small quantities of brown fluid frequently and was in great pain The tongue was dry and furred The abdomen was flat, the pain being most severe in the region of the umbilicus There was no rigidity Palpation, however, revealed forcible contraction of the intestine, accompanied by borborygmi, although no visible peristalsis was present Temperature, pulse, and respiration normal

I made a diagnosis of acute small intestine obstruction of unknown origin I opened the abdomen about one hour after admission Some coils of rather distended small intestine first appeared A movable lump was felt about 2 inches below the umbilicus When drawn into the wound it proved to be an ileo-ileal intussusception The mass was easily reduced, but a considerable length of gut was obviously gangrenous owing to thrombosis of the mesenteric vessels It was found necessary to resect 5 feet of the ileum and to do an end-to-end anastomosis

For 48 hours after the operation the patient's condition was desperate, the pulse being quite uncountable and only just perceptible Two intravenous saline injections of 2 pints each were given Eserin and turpentine enemata were begun immediately and continued four-hourly The colour of the vomiting changed from brown to biliary, the bowels began to act, and the patient's condition gradually improved

Convalescence was complicated by a troublesome *Bacillus coli* infection of the wound together with thrombosis of the left internal saphenous vein She was discharged on April 24th The bowels were then acting regularly and have done so up to June 28th The wound is now healed and the swelling of the leg has subsided The interior of the apex of the intussusception showed a gangrenous, adenomatous polyp, about the size of a cherry

I am indebted to Mr J Lacy Firth, into whose ward the patient was admitted, for permission to publish this case

Medical Societies.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND

A MEETING of this Society was held in Marischal College, Aberdeen, on July 9th and 10th, Prof T SHENNAN and J CRUICKSHANK in the chair

T DALLING (London) said that lamb dysentery could be produced by feeding lambs with cultures of *coli* from infected animals plus cultures of *Cl Welchii* or with larger doses of *welchii* alone In large scale field experiments, mostly in the border counties, very satisfactory protection was obtained (*a*) by immunising the pregnant ewes with *coli* vaccine along with *welchii* toxin-antitoxin mixtures, or (*b*) by dosing new-born lambs with *coli* and *welchii* antisera —J W McLEOD (Leeds) described an anaerobic bacillus similar to Pfeiffer's organism obtained from blood and cerebro-spinal fluid which produced amounts of hydrogen peroxide demonstrable by the usual cadmium-iodide starch and titanium reagents —C H BROWNING, J B COHEN, S ELLINGWORTH, and R GUBRANSEN (Glasgow and Leeds) gave an account of the trypanocidal activity of a new series of aminostyryl and aminoanil quinoline compounds Though unsuitable for intravenous injection they gave remarkable curative results with *T brucei* in the acute disease in mice and the chronic infection in rabbits They have much less effect in vitro —A E BOYCOTT and C PRICE-JONES (London) found that Gaertner's bacillus fed to rats in adequate doses penetrated to the spleen in all cases in two or three days and was then slowly got rid of, only about 15 per cent of animals remaining infected after two months The majority of animals develop agglutinins *B pyocyaneus* and *B typhosus* fail to get a lodgment in the spleen when fed in the same way —J A ARKWRIGHT (London) showed that vaccines made from the smooth form of paratyphoid A were more efficient than those prepared from the rough variety.—J C KERRIN and J CRUICKSHANK (Aberdeen) described four small epidemics of dysentery in Aberdeen, mostly in children, due to Sonne's dysentery bacillus which appears to be identical with *B coli anaerogenes* —C H WHITTLE (Cambridge) had found the inulin fermentation of pneumococci an unreliable character —J GORDON (Leeds) improves media for the growth of the gonococcus by the addition of taurine —P HARTLEY (London) noted that when nearly neutral mixtures of diphtheria toxin and antitoxin are made in the manner of Ramon the precipitates produced are very small in bulk, contain about 0 5 per cent of the original nitrogen, and are mostly composed of magnesium hydrogen phosphate, the actual antigen cannot constitute more than 10 per cent of the whole precipitate and must be present in a high state of purity Its antigenic value is preserved if it is diluted for injection with saline, but considerably deteriorated if broth meat extracts or carbolic are used —R A O'BRIEN (London) pointed out that the minute amount of toxin in a Schick test injection can act as an immunising antigen in animals and children —J McINTOSH and S L. BAKER (London) had obtained very variable results in experiments on the filterability of the Rous tumour Passage seemed to raise the infectivity considerably but differences in the physical condition of the tumour and in the viscosity of the extracts made differences which could not be controlled Digesting with acid trypsin gave a more active filtrate —A LEITCH (London) had also had much difficulty in transferring "mouse sarcoma 37" by cell-free filtrates Drying killed the tumour —T J MACKIE and E N McDERMOTT (Edinburgh) described the spirillum they had obtained from a case of rat-bite fever, in the rat the organism passes in the tears to the nose and mouth and is so inoculated by the teeth —J O W BARRATT (London), from an analysis of the mode of action of hirudin, concluded that it acted on thrombin

—F EARLAM and E E GLYNN (Liverpool) pointed out that the maximum incidence of post-operative pulmonary thrombosis was about the tenth day and they had found that the blood platelets begin to increase directly after an operation and reach their maximum at the same time, the coagulation time is diminished proportionately to the increase in platelets —K EDGECOMBE and E E GLYNN (Liverpool) said that in blood transfusion the effect of the recipient's serum on the donor's cells was not the only test of importance, some donors might have such a high agglutinating titre that their serum, even when diluted in the blood of the recipient, might agglutinate his cells The only safe procedure was to cross-agglutinate the cells and serum of the recipient and the proposed donor —J MARNOCH and T SHENNAN (Aberdeen) discussed thrombo-angeitis obliterans —A LYALL (Aberdeen) dealt with the protein ratio in relation to the acidosis of diabetes —J S DUNN and C J POLSON (Manchester) in experiments on uric acid nephritis found that very large doses of urate intravenously were excreted in the kidneys, passed down the tubules, and then by concentration and acidification was precipitated in the ascending limb of Henle's loop where they caused necrosis of the epithelium The urea retention observed is due to urea leaking back from the glomerular filtrate through the damaged epithelium No chronic results were obtained by the repeated exhibition of smaller doses —G S WILLIAMSON and I H PEARSE (London) urged that the "intercellular channels" between the epithelial cells of the thyroid alveoli were cells joining their microcapillary system to the general reticulo-endothelial apparatus of the organ —G LENTHAL CHEATLE (London) demonstrated the various forms and modes of origin of the extra- and intra-elastica fibro-adenomata of the breast He also showed how acquired adhesions in bursæ arose by the organisation of strands of lymph —A W DOWNIE and J CRUICKSHANK (Aberdeen) had planted stones, lead shot, gall-stones, glass beats, &c, in the gall-bladders of guinea-pigs and had failed to convince themselves that the epithelial growth which was obtained in some instances was malignant in nature —D LEITCH exhibited some of his own specimens and reaffirmed his conviction that they demonstrated cancer —J MARNOCH (Aberdeen) showed a leiomyoma of the stomach from a man of 57 with a five years' history of intermittent vomiting and hæmorrhage from an ulcer on the mucosal surface —E F FINCH and H H GLEAVE (Sheffield) described a case of osteoclastoma (myeloid sarcoma) of the femur with a known history of eight years, after the leg was finally amputated recurrence occurred in the stump and the patient died with pulmonary metastases of the typical histological structure —M J STEWART (Leeds), from an analysis of stomach material removed at operation in some 300 patients, concluded that about 9 per cent of chronic gastric ulcers show cancer and that about 10 per cent of cancers show old ulceration The most important criterion of chronic ulceration is destruction of the muscular coat Misplaced epithelium and heterotopias have misled many observers into unjustified diagnoses of cancer —J S YOUNG and S V TELFER (Glasgow) described a case of renal calculus with epithelioma infiltrating into the kidney —T SHENNAN (Aberdeen) discussed a series of tumours of lung and mediastinum and laid stress on the difficulty of distinguishing between the sarcomata and carcinomata —S McDONALD (Newcastle) showed how it was possible to make a histological diagnosis of pneumonia in a body exhumed many weeks after burial —N D BALL (London) showed an epithelial tumour growing on the spleen of a rabbit which looked like appendix tissue —J P McGOWAN (Aberdeen) various conditions of comparative blood pathology, H J PARISH (London) coccal forms of the diphtheria bacillus, S C DYKE (Wolverhampton) a bony tumour of the breast, D F CAPPELL (Glasgow) a dissecting aneurysm of the aorta, a retroperitoneal ganglionic neuroma and partial necrosis of liver with tumour formation, J M BEATTIE (Liverpool) specimens of experimental foot-and-mouth disease; E E GLYNN (Liverpool) a case of ? sprue and some exceptionally large biliary tuberculous abscesses, T SHENNAN (Aberdeen) various pathological specimens and some useful post-mortem instruments, methods of storing slides, dehydrating alcohol, &c, and C H. USHER (Glasgow) some eye preparations

---

ROYAL SOCIETY OF MEDICINE.

SECTION OF ANÆSTHETICS

THE first of two morning sessions of this section, which have been arranged as a welcome to visitors from the United States and Canada, was held on July 13th. Dr F E SHIPWAY, President of the Section, took the chair

The PRESIDENT, in welcoming the Transatlantic visitors, alluded to the various discoveries made in the domain of anæsthetics by workers in the States

The Physiology of Respiration in Relation to Anæsthesia

Prof J S HALDANE read a paper on Some Bearings of the Physiology of Respiration on the Administration of Anæsthetics The anæsthetic administered, he said, acted on the whole central nervous system, and modified the mechanism of various physiological processes, unless these effects were controlled they might be harmful, even dangerous When the anæsthetic was pushed, the lips were apt to lose their bright red colour and to become bluish, though there was no cessation, nor even marked diminution, of breathing. This change of colour indicated that the blood was not being fully oxygenated in the lungs Another symptom of defective oxygenation was Cheyne-Stokes breathing Anomalous effects could be explained by assuming that the oxygen percentages in the different alveoli varied considerably, as alveoli with oxygen content considerably lower than normal might be unable to saturate the blood beyond a lower degree than normal, and the depth of breathing became much diminished But the irregular distribution of air in the alveoli did not interfere with the amount of CO_2 in the mixed arterial blood When in the alveolar air 14 per cent of oxygen was present, the blood was nearly saturated—i e, it reached 97 per cent of saturation If for any reason breathing became shallower, even if it were of increased frequency, symptoms of want of oxygen were produced, the shallow breathing having merely accentuated the differences existing owing to variations in different alveoli Prof Haldane described various experiments made on himself While lying in bed he was able, he said, regularly to cause Cheyne-Stokes breathing by raising his breathing rate from 7 to 20 per minute

When pushed to full anæsthesia anæsthetics caused diminution in the vigour of the patient's responses to respiratory stimuli and so there was diminished oxygenation of the blood It was apt to be concluded that the continuance of breathing during anæsthesia showed that there was no sign of stoppage, and blueness of lips was likely to be attributed to defective heart rather than to the defective breathing, which caused it The importance of maintaining the normal degree of oxygenation of the arterial blood was generally not fully grasped, if it was kept appreciably below normal in the ordinary person, headaches and general depression gradually asserted themselves and persisted long after exposure to oxygen-lack had ended This he considered, caused some damage—not necessarily gross—of the central nervous system, some alteration in its molecular structure Yet there might be no evident danger actually during anæsthesia, the effects being manifest after anæsthesia was over An easy way to avoid them was by adding a small amount of CO_2 to the inspired air, as that was a natural stimulant to breathing A good method was

The spleen weighed 1 lb 7 oz , was 7¾ in in length, and histologically showed the usual reticulo-endothelial proliferation, engorged sinuses, and red cell phagocytosis

Orahovats has demonstrated that, in a normal animal, the red cells of the blood in the spleen pulp are more vulnerable to the lytic action of hypotonic saline and less vulnerable to that of saponin than are the red cells in the general circulation This result was obtained in the blood leaving by the vein after ligature of the splenic artery and stimulation of the splenic nerve By this manœuvre red cells were obtained direct from the spleen pulp, cells merely passing through the organ and escaping, its " filter-bed " being eliminated Prof Barcroft inclines to the view that this increased fragility is not acquired during the sojourn of the cells in the spleen pulp, but that cells which are fragile from some unknown physiological cause are retained by the spleen acting as a differential filter

In the case we report, the cells of the blood aspirated from the splenic vein were more fragile than the abnormally fragile cells of the general circulation It is not unlikely that the blood we obtained came from the spleen pulp, for ligature of the pedicle would probably be sufficient stimulus to the splenic nerve, and the delay between ligature and removal would allow sufficient time, for the splenic sinuses to deplete themselves It is obvious that such a result as we obtained in a diseased organ might very easily have been misconstrued if the fundamental physiological facts regarding normal fragility had not been available

ACUTE INTUSSUSCEPTION IN AN ADULT

By F W Widgery, F R C S Eng ,

SENIOR RESIDENT MEDICAL OFFICER, BRISTOL GENERAL HOSPITAL.

The case below is thought worthy of record because of the unusual occurrence of the acute condition in the adult Furthermore, it illustrates the extraordinary power possessed by some individuals of recovery from the moribund state

Mrs D , aged 43, was admitted to the Bristol General Hospital at 10 30 P M on March 13th, 1926, with a history of four days' severe and continuous abdominal pain and vomiting, of sudden onset Her previous history was of no account

The condition on admission was as follows Her expression was anxious , she vomited small quantities of brown fluid frequently and was in great pain The tongue was dry and furred The abdomen was flat, the pain being most severe in the region of the umbilicus There was no rigidity Palpation, however, revealed forcible contraction of the intestine, accompanied by borborygmi, although no visible peristalsis was present Temperature, pulse, and respiration normal

I made a diagnosis of acute small intestine obstruction of unknown origin I opened the abdomen about one hour after admission Some coils of rather distended small intestine first appeared A movable lump was felt about 2 inches below the umbilicus When drawn into the wound it proved to be an ileo-ileal intussusception The mass was easily reduced, but a considerable length of gut was obviously gangrenous owing to thrombosis of the mesenteric vessels It was found necessary to resect 5 feet of the ileum and to do an end-to-end anastomosis

For 48 hours after the operation the patient's condition was desperate, the pulse being quite uncountable and only just perceptible Two intravenous saline injections of 2 pints each were given Eserin and turpentine enemata were begun immediately and continued four-hourly The colour of the vomiting changed from brown to biliary, the bowels began to act, and the patient's condition gradually improved

Convalescence was complicated by a troublesome *Bacillus coli* infection of the wound together with thrombosis of the left internal saphenous vein She was discharged on April 24th The bowels were then acting regularly and have done so up to June 28th The wound is now healed and the swelling of the leg has subsided The interior of the apex of the intussusception showed a gangrenous, adenomatous polyp, about the size of a cherry

I am indebted to Mr J Lacy Firth, into whose ward the patient was admitted, for permission to publish this case

Medical Societies.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND

A meeting of this Society was held in Marischal College, Aberdeen, on July 9th and 10th, Prof. T Shennan and J Cruickshank in the chair

T Dalling (London) said that lamb dysentery could be produced by feeding lambs with cultures of *coli* from infected animals plus cultures of *Cl Welchii* or with larger doses of *welchii* alone In large scale field experiments, mostly in the border counties, very satisfactory protection was obtained (*a*) by immunising the pregnant ewes with *coli* vaccine along with *welchii* toxin-antitoxin mixtures, or (*b*) by dosing new-born lambs with *coli* and *welchii* antisera —J W McLeod (Leeds) described an anaerobic bacillus similar to Pfeiffer's organism obtained from blood and cerebro spinal fluid which produced amounts of hydrogen peroxide demonstrable by the usual cadmium-iodide starch and titanium reagents —C H Browning, J B Cohen, S Ellingworth, and R Gubransen (Glasgow and Leeds) gave an account of the trypanocidal activity of a new series of aminostyryl and aminoanil quinoline compounds Though unsuitable for intravenous injection they gave remarkable curative results with *T brucei* in the acute disease in mice and the chronic infection in rabbits They have much less effect in vitro —A. E Boycott and C Price Jones (London) found that Gaertner's bacillus fed to rats in adequate doses penetrated to the spleen in all cases in two or three days and was then slowly got rid of, only about 15 per cent of animals remaining infected after two months The majority of animals develop agglutinins *B pyocyaneus* and *B typhosus* fail to get a lodgment in the spleen when fed in the same way —J A Arkwright (London) showed that vaccines made from the smooth form of paratyphoid A were more efficient than those prepared from the rough variety —J C Kerrin and J Cruickshank (Aberdeen) described four small epidemics of dysentery in Aberdeen, mostly in children, due to Sonne's dysentery bacillus which appears to be identical with *B coli anaerogenes* —C H Whittle (Cambridge) had found the inulin fermentation of pneumococci an unreliable character —J Gordon (Leeds) improves media for the growth of the gonococcus by the addition of taurine —P Hartley (London) noted that when nearly neutral mixtures of diphtheria toxin and antitoxin are made in the manner of Ramon the precipitates produced are very small in bulk, contain about 0 5 per cent of the original nitrogen, and are mostly composed of magnesium hydrogen phosphate , the actual antigen cannot constitute more than 10 per cent of the whole precipitate and must be present in a high state of purity Its antigenic value is preserved if it is diluted for injection with saline, but considerably deteriorated if broth meat extracts or carbolic are used —R A O'Brien (London) pointed out that the minute amount of toxin in a Schick test injection can act as an immunising antigen in animals and children —J McIntosh and S L. Baker (London) had obtained very variable results in experiments on the filterability of the Rous tumour Passage seemed to raise the infectivity considerably but differences in the physical condition of the tumour and in the viscosity of the extracts made differences which could not be controlled Digesting with acid trypsin gave a more active filtrate —A Leitch (London) had also had much difficulty in transferring " mouse sarcoma 37 " by cell-free filtrates Drying killed the tumour —T J Mackie and E N McDermott (Edinburgh) described the spirillum they had obtained from a case of rat-bite fever , in the rat the organism passes in the tears to the nose and mouth and is so inoculated by the teeth —J O W Barratt (London), from an analysis of the mode of action of hirudin, concluded that it acted on thrombin

—F. Earlam and E E Glynn (Liverpool) pointed out that the maximum incidence of post-operative pulmonary thrombosis was about the tenth day and they had found that the blood platelets begin to increase directly after an operation and reach their maximum at the same time; the coagulation time is diminished proportionately to the increase in platelets —K Edgecombe and E E Glynn (Liverpool) said that in blood transfusion the effect of the recipient's serum on the donor s cells was not the only test of importance, some donors might have such a high agglutinating titre that their serum, even when diluted in the blood of the recipient, might agglutinate his cells The only safe procedure was to cross-agglutinate the cells and serum of the recipient and the proposed donor —J Marnoch and T Shennan (Aberdeen) discussed thrombo-angeitis obliterans —A Lyall (Aberdeen) dealt with the protein ratio in relation to the acidosis of diabetes —J. S Dunn and C. J Polson (Manchester) in experiments on uric acid nephritis found that very large doses of urate intravenously were excreted in the kidneys, passed down the tubules, and then by concentration and acidification was precipitated in the ascending limb of Henle's loop where they caused necrosis of the epithelium The urea retention observed is due to urea leaking back from the glomerular filtrate through the damaged epithelium. No chronic results were obtained by the repeated exhibition of smaller doses —G. S Williamson and I H Pearse (London) urged that the "intercellular channels" between the epithelial cells of the thyroid alveoli were cells joining their microcapillary system to the general reticulo-endothelial apparatus of the organ —G. Lenthal Cheatle (London) demonstrated the various forms and modes of origin of the extra- and intra-elastica fibro-adenomata of the breast He also showed how acquired adhesions in bursæ arose by the organisation of strands of lymph —A W. Downie and J Cruickshank (Aberdeen) had planted stones, lead shot gall-stones, glass beats, &c, in the gall-bladders of guinea-pigs and had failed to convince themselves that the epithelial growth which was obtained in some instances was malignant in nature —D Leitch exhibited some of his own specimens and reaffirmed his conviction that they demonstrated cancer —J Marnoch (Aberdeen) showed a leiomyoma of the stomach from a man of 57 with a five years' history of intermittent vomiting and hæmorrhage from an ulcer on the mucosal surface —E F Finch and H H Gleave (Sheffield) described a case of osteoclastoma (myeloid sarcoma) of the femur with a known history of eight years, after the leg was finally amputated recurrence occurred in the stump and the patient died with pulmonary metastases of the typical histological structure —M J Stewart (Leeds), from an analysis of stomach material removed at operation in some 300 patients, concluded that about 9 per cent of chronic gastric ulcers show cancer and that about 19 per cent of cancers show old ulceration The most important criterion of chronic ulceration is destruction of the muscular coat Misplaced epithelium and heterotopias have misled many observers into unjustified diagnoses of cancer —J. S Young and S V Telfer (Glasgow) described a case of renal calculus with epithelioma infiltrating into the kidney. —T Shennan (Aberdeen) discussed a series of tumours of lung and mediastinum and laid stress on the difficulty of distinguishing between the sarcomata and carcinomata —S McDonald (Newcastle) showed how it was possible to make a histological diagnosis of pneumonia in a body exhumed many weeks after burial —N D Ball (London) showed an epithelial tumour growing on the spleen of a rabbit which looked like appendix tissue —J. P. McGowan (Aberdeen) various conditions of comparative blood pathology, H J Parish (London) coccal forms of the diphtheria bacillus, S C Dyke (Wolverhampton) a bony tumour of the breast, D F Cappell (Glasgow) a dissecting aneurysm of the aorta, a retroperitoneal ganglionic neuroma and partial necrosis of liver with tumour formation; J M. Beattie (Liverpool) specimens of experimental foot-and-mouth disease; E E Glynn (Liverpool) a case of ? sprue and some exceptionally large biliary tuberculous abscesses; T Shennan (Aberdeen) various pathological specimens and some useful post-mortem instruments, methods of storing slides, dehydrating alcohol, &c; and C H Usher (Glasgow) some eye preparations

In the case we report, the cells of the blood aspirated from the splenic vein were more fragile than the abnormally fragile cells of the general circulation It is not unlikely that the blood we obtained came from the spleen pulp, for ligature of the pedicle would probably be sufficient stimulus to the splenic nerve, and the delay between ligature and removal would allow sufficient time, for the splenic sinuses to deplete themselves It is obvious that such a result as we obtained in a diseased organ might very easily have been misconstrued if the fundamental physiological facts regarding normal fragility had not been available

ACUTE INTUSSUSCEPTION IN AN ADULT

By F W Widgery, F R C S Eng ,

SENIOR RESIDENT MEDICAL OFFICER, BRISTOL GENERAL HOSPITAL.

The case below is thought worthy of record because of the unusual occurrence of the acute condition in the adult Furthermore, it illustrates the extraordinary power possessed by some individuals of recovery from the moribund state

Mrs D , aged 43, was admitted to the Bristol General Hospital at 10 30 P M on March 13th, 1926, with a history of four days' severe and continuous abdominal pain and vomiting, of sudden onset Her previous history was of no account

The condition on admission was as follows Her expression was anxious , she vomited small quantities of brown fluid frequently and was in great pain The tongue was dry and furred The abdomen was flat, the pain being most severe in the region of the umbilicus There was no rigidity Palpation, however, revealed forcible contraction of the intestine, accompanied by borborygmi, although no visible peristalsis was present Temperature, pulse, and respiration normal

I made a diagnosis of acute small intestine obstruction of unknown origin I opened the abdomen about one hour after admission Some coils of rather distended small intestine first appeared A movable lump was felt about 2 inches below the umbilicus When drawn into the wound it proved to be an ileo-ileal intussusception The mass was easily reduced, but a considerable length of gut was obviously gangrenous owing to thrombosis of the mesenteric vessels It was found necessary to resect 5 feet of the ileum and to do an end-to-end anastomosis

For 48 hours after the operation the patient's condition was desperate, the pulse being quite uncountable and only just perceptible Two intravenous saline injections of 2 pints each were given Eserin and turpentine enemata were begun immediately and continued four-hourly The colour of the vomiting changed from brown to biliary, the bowels began to act, and the patient's condition gradually improved

Convalescence was complicated by a troublesome *Bacillus coli* infection of the wound together with thrombosis of the left internal saphenous vein She was discharged on April 24th The bowels were then acting regularly and have done so up to June 28th The wound is now healed and the swelling of the leg has subsided The interior of the apex of the intussusception showed a gangrenous, adenomatous polyp, about the size of a cherry

I am indebted to Mr J Lacy Firth, into whose ward the patient was admitted, for permission to publish this case

Medical Societies.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND

A meeting of this Society was held in Marischal College, Aberdeen, on July 9th and 10th, Prof T Shennan and J Cruickshank in the chair

T Dalling (London) said that lamb dysentery could be produced by feeding lambs with cultures of *coli* from infected animals plus cultures of *Cl Welchii* or with larger doses of *welchii* alone In large scale field experiments, mostly in the border counties, very satisfactory protection was obtained (*a*) by immunising the pregnant ewes with *coli* vaccine along with *welchii* toxin-antitoxin mixtures, or (*b*) by dosing new-born lambs with *coli* and *welchii* antisera —J W McLeod (Leeds) described an anaerobic bacillus similar to Pfeiffer's organism obtained from blood and cerebrospinal fluid which produced amounts of hydrogen peroxide demonstrable by the usual cadmium-iodide starch and titanium reagents —C H Browning, J B Cohen, S Ellingworth, and R Gubransen (Glasgow and Leeds) gave an account of the trypanocidal activity of a new series of aminostyryl and aminoanil quinoline compounds Though unsuitable for intravenous injection they gave remarkable curative results with *T brucei* in the acute disease in mice and the chronic infection in rabbits They have much less effect in vitro —A E Boycott and C Price-Jones (London) found that Gaertner's bacillus fed to rats in adequate doses penetrated to the spleen in all cases in two or three days and was then slowly got rid of, only about 15 per cent of animals remaining infected after two months The majority of animals develop agglutinins *B pyocyaneus* and *B typhosus* fail to get a lodgment in the spleen when fed in the same way —J A Arkwright (London) showed that vaccines made from the smooth form of paratyphoid A were more efficient than those prepared from the rough variety —J C Kerrin and J Cruickshank (Aberdeen) described four small epidemics of dysentery in Aberdeen, mostly in children, due to Sonne's dysentery bacillus which appears to be identical with *B coli anaerogenes* —C H Whittle (Cambridge) had found the inulin fermentation of pneumococci an unreliable character.—J Gordon (Leeds) improves media for the growth of the gonococcus by the addition of taurine —P Hartley (London) noted that when nearly neutral mixtures of diphtheria toxin and antitoxin are made in the manner of Ramon the precipitates produced are very small in bulk, contain about 0 5 per cent of the original nitrogen, and are mostly composed of magnesium hydrogen phosphate , the actual antigen cannot constitute more than 10 per cent of the whole precipitate and must be present in a high state of purity Its antigenic value is preserved if it is diluted for injection with saline, but considerably deteriorated if broth meat extracts or carbolic are used —R A O'Brien (London) pointed out that the minute amount of toxin in a Schick test injection can act as an immunising antigen in animals and children —J McIntosh and S L Baker (London) had obtained very variable results in experiments on the filterability of the Rous tumour Passage seemed to raise the infectivity considerably but differences in the physical condition of the tumour and in the viscosity of the extracts made differences which could not be controlled Digesting with acid trypsin gave a more active filtrate —A Leitch (London) had also had much difficulty in transferring " mouse sarcoma 37 " by cell-free filtrates Drying killed the tumour —T J Mackie and E N McDermott (Edinburgh) described the spirillum they had obtained from a case of rat-bite fever , in the rat the organism passes in the tears to the nose and mouth and is so inoculated by the teeth —J O W Barratt (London), from an analysis of the mode of action of hirudin, concluded that it acted on thrombin by carrying out a less thorough washing process On many occasions recently he had returned cylinders of nitrous oxide because they did not pass satisfactorily the clinical reactions of the patient and had an unusual smell, though the latter should not be relied upon, as the nose lost some of its sensitiveness when in the presence of the same aroma for several hours He related one or two cases in the States in which the actual cautery set fire to the vapour in the patient's air passages One such patient with carcinoma of the tongue was given ether by the open method and the cautery applied, when an explosion occurred which fractured the base of the skull and projected the eyes on to the cheeks, at the same time producing a hæmorrhage in the air passages

Dr **WESLEY BOURNE** described some work he did on this subject in the Department of Pharmacology. Glasgow ascertaining the effects of known quantities of impurities added to otherwise pure anæsthetic ether

Dr **MCMECHAN** said he hoped the report of the Committee of which Dr. Blomfield spoke would not be allowed to pass unchallenged In the States certainly the standard of purity insisted on for these drugs was not nearly high enough For nitrous oxide a purity of at least 98 or 99 per cent should be required He added one or two more cases of explosion to those mentioned by Dr McKesson In the case of certain forms of anæsthetic it was very unsafe to allow the patient to light and smoke a cigarette soon after the operation. as so many liked to do

Mr **A. H WELLESLEY**, speaking as a manufacturer, said it was possible to reach an average purity of 2 per cent throughout the cylinder of nitrous oxide.

Dr **WILSON** spoke of a case in which fulminating pneumonia occurred 18 hours after nitrous oxide administration and he knew two cases in this country in which a fatal explosion in the mouth occurred

EDINBURGH OBSTETRICAL SOCIETY

A MEETING of this Society was held on June 9th Dr R W **JOHNSTONE** the President, in the chair Papers were read dealing with the pathology and treatment of

Concealed Accidental Hæmorrhage

Dr J **HEWITT** began by considering the common explanations of the retention of blood within the uterus He agreed with Gordon Ley that non-dilatation of the cervix adhesion of the membranes around the os pressure on the lower uterine segment by the presenting part or rupture of the hæmorrhage into the amniotic sac did not adequately or correctly explain the condition In addition to these objections raised by Ley Dr Hewitt quoted Barnes s views on the supposed adhesion of the membranes and added the personal observation that in many cases the blood-clot was entirely retroplacental and that, even when bleeding extended beyond the placental margin the blood often travelled upwards towards the fundus and thus never even reached the lower segment

In view of the inadequacy of these theories he said it was not surprising that the opinion arose that the blood was retained because the uterus was unable to expel it the uterine muscle being described as inert atonic or paralytic

His own view was that the uterus was temporarily unable to undergo rhythmic contractions because it was already in a state of sustained and painful tetanic contraction His reasons for this belief emerged in answer to the question Why cannot the fœtal parts be palpated in the cases of concealed accidental hæmorrhage? Rigidity of the parietes was not responsible as was shown by the fact that in these cases palpation still yielded negative results when the patient was deeply anæsthetised and even after the abdomen had been opened in the course of a Cæsarean section Intervention of placenta and blood-clot occurred in some cases; but in others, in which palpation had been negative manual exploration of the uterus during Cæsarean section or at autopsy often discovered the placenta on the posterior wall A hard tender, well-defined uterus was incompatible with the description "atonic" and in concealed hæmorrhage the membranes were tense, which would be impossible in an inert organ Dr Hewitt adduced Sir James Mackenzie s dictum that a hollow muscular organ may be distended indefinitely without producing pain until a contraction is set up, in support of his opinion that the uterus was in a state of tonic contraction

Dr S J. **CAMERON** gave his views on the rational treatment theory based on Dr Hewitt's It was most important he said to realise that in concealed accidental hæmorrhage the patient's life was endangered more by shock than by hæmorrhage The amount of blood lost in a fatal case was often much less than was lost by a patient with placenta prævia who survived As regards the relative importance of shock and hæmorrhage, there was a close similarity between concealed accidental hæmorrhage and acute inversion of the uterus. If bleeding was considered the more important factor, Cæsarean section should be performed on every occasion but Dr Cameron did not accept the opinion that it was Perhaps the most generally practised method of treatment was to pack the vagina It was claimed that an efficient vaginal plug arrested the flow of blood through the uterine arteries but he did not believe it possible by any method short of actual ligature or clamp to arrest or perceptibly diminish the flow of blood through these vessels. which had a very wide range of movement and merely rose to a high level when packing was introduced into the vagina Moreover, a liberal blood-supply still reached the uterus by the ovarian arteries which, during pregnancy, were not much smaller than the uterine arteries and which with the latter, formed an unconstricted "utero-ovarian loop' on the margins of the uterus between the aorta above and the internal iliac artery below

In treating cases of concealed accidental hæmorrhage said Dr Cameron the patient should be guarded from shock by administering large and repeated doses of morphia during the acute stage When this stage has passed but not before, labour pains were stimulated by pituitary extract If the patient did not improve after morphia had been given he performed Cæsarean section because in his experience one of two events had occurred—viz. a recurrence of bleeding, or rupture of the uterus So far he had never been compelled to remove the uterus on account of atony He did not perform vaginal Cæsarean section because (1) the shock was not less than abdominal Cæsarean section, (2) it was impossible to inspect the uterus for rupture (3) hæmorrhage was less easily controlled. and (4) towards the end of pregnancy extraction of the child might be difficult

---

MEDICAL INSTRUCTION BY PAMPHLETS — The Wesleyan and General Assurance Society, whose headquarters are at Birmingham, has been issuing through its health service bureau a series of pamphlets on matters of health and hygiene More than 600 medical officers of health and 150 educational authorities have already made use of these pamphlets and the three recently published should be as popular as their predecessors The one on whooping-cough usefully calls attention to the seriousness of this disease which the public has never respected as it respects the other acute specific fevers—perhaps because there is no rash. The second deals with rheumatism On the one hand it refers to the dangers and prevention of rheumatic infection in children wisely calling attention to chorea as one of the manifestations, and on the other describes rheumatism as it affects older people. The third is concerned with the care of the teeth and has a striking cover depicting a crocodile with its mouth open to show a fine set of teeth with the slogan "The Crocodile Lives 200 Years" On the backs of the pamphlets are thoughts on health culled from bygone authors and these contain many useful maxims to arrange that the patient should re-breathe a portion of his own expired air In the presence of shallow breathing all parts of the lung were not duly expanded, and hence there was a deficient general oxygenation Mere increase in the rate of breathing, without an added depth, was relatively useless Too large a proportion of CO_2 was washed out of the blood, and this caused alkalosis, the consequences of which to the circulation was very serious It was desirable to add a small amount of CO_2 to the air breathed by patients after operation, especially if the operation had been prolonged This also brought about more rapid elimination of the anæsthetic from the tissues Forced breathing—as distinct from deep breathing—removed too large a quantity of CO_2 from the blood and thus brought about alkalosis

Even when CO_2 is used a definite time is required to bring the patient fairly under the anæsthetic To do this, not only the blood but the tissues must be saturated sufficiently, and each quota of blood entering and leaving the lungs must contain a certain amount of anæsthetic until the required degree was reached It had been found that the circulation of the blood through the central nervous system was more rapid than through any other part of the organism An instrument was needed which would regulate the proportion of the anæsthetic and the amount of CO_2 in the air being inspired by the patient, as was done in the case of the instrument used for miners who inhaled noxious gases in the pits

Discussion

Dr S R **Wilson** (Manchester) said he considered that the occurrence of cyanosis in any form of anæsthesia was unsound Sometimes, in abdominal operations, when the patient's lips and ears remained a healthy pink, the lips of the abdominal wound were blue Every method of anæsthetisation implied some degree of re-breathing Sometimes the surgeon's manipulations greatly reduced the respiration of the patient, for example, when he put a bridge under the thorax when doing a gall-bladder operation, it being thus brought down occasionally to only 40 per cent of the normal He considered that the reflex and sensory side of the subject ought to be more fully considered

Dr **McMechan** (U S A) said Major Schroeder's experience in the States was that at the height of 25,000 to 30,000 ft it was possible to study all the phenomena of analgesia Aviators found deep breathing a remedy for many of the ills they experienced at great heights He referred to the work of de Sajous, of Philadelphia, who insisted that there was a basic phenomenon connected with the adrenalin secretion underlying the function of respiration That authority considered that unless adrenalin was actively secreted and was present in the blood stream, it was difficult for the physiology of respiration to be carried on efficiently A prolonged operation sometimes annihilated the adrenalin reserve, and then it was difficult to maintain the vital processes There was a type of patient who was tending towards alkalosis even before anæsthesia was commenced

Prof **Haldane** replied at some length He said the blue lips of the abdominal wound referred to could be rendered pink by exposing them to an atmosphere containing 5 per cent of CO_2, or by bathing them with saline solution He thought CO_2 would also overcome most of the reflex difficulties The lowering of the alkaline reserve in the blood should not be regarded, he thought, as evidence of acidosis He had personally studied the effects on the organism of being in an atmospheric pressure equal to that at a height of 25,000 ft, and in himself the early symptoms were a shakiness in his writing when making the records and a distinct weakening of memory, so that it was necessary to at once enter a figure, or he would forget it

Dr J **Blomfield** gave an address on

Recent Investigations concerning Nitrous Oxide and the Ignition Points of Certain Anæsthetic Vapours

Searching for something to lay before the visitors from over the Atlantic which could have escaped even their indefatigable inquiries into all anæsthetic questions, he had been fortunate in having at his disposal the work of a committee whose very existence was probably unknown in Canada and the United States This was the Anæsthetics Committee set up jointly by the Medical Research Council and the Anæsthetic Section of the Royal Society of Medicine His remarks would be based almost entirely on the work, partly done and partly still in progress, of this Committee, which consisted of Dr H H Dale, Prof F G Donnan Prof M S Pembrey, Dr F E Shipway, Dr C F. Hadfield, and himself

Although a good deal of investigation had been done by the Committee on the impurities of ether and on the clinical and laboratory aspects of acetylene, ethylene, and propylene, Dr Blomfield dealt chiefly with nitrous oxide and with the work which Prof H B Dixon had carried out for the Committee on the ignition points of various vapours A number of samples of nitrous oxide were examined which were taken from cylinders from which patients had inhaled the anæsthetic and had afterwards exhibited unusual symptoms The samples had been supplied by various anæsthetists who had found reason to complain of the gas The outstanding fact which resulted from a large number of examinations was that in no instance was there present any one of the formidable impurities which were suspected to be the cause of the symptoms That is to say, no halogen, carbon monoxide, or nitric oxide was found in any instance The impurity most often found was nitrogen, in percentage varying from 2 to 10 It was also made evident by the various experiments that when this gas is present as an impurity in a cylinder of nitrous oxide it is in its highest proportion in the first quantities of gas that escape from the cylinder, and this disproportion between early and later samples is the most marked the more nearly vertical the position in which the cylinder is employed

Dr Blomfield described the experiments which Prof Dixon had carried out on the ignition points of ether, of ethylene, and of propylene He alluded to the practical importance of Prof Dixon's determinations and in particular to the fact that ignition of ether did not require, as anæsthetists had been apt to suppose, a red-hot metal or an open flame When used in ways in which it was often used to day the ignition point of ether vapour was well below that required to bring metal to a red heat, and it was disregard of this fact that had been responsible for several disasters The experiments had also brought out the fact that a combination of ethylene and nitrous oxide was more easily ignited than one of ethylene and oxygen—another unexpected finding With regard to acetylene, the Committee had found that the measures which alone succeeded in removing the acetone present with this anæsthetic were of a kind to render the clinical use of acetylene most inconvenient, even apart from the disadvantage of the unpleasant smell of this agent

Prof **Haldane** said this contribution brought the subject of anæsthesia into close relation with that of coal-mining in the respiratory aspect In connexion with rescue apparatus used in mines there was at first considerable difficulty experienced owing to the presence of a considerable proportion of nitrogen as an impurity in the oxygen This gradually accumulated, and in time became a dangerous factor in suffocation, the miner using and relying upon a closed cavity when perhaps half a mile below the surface Nowadays there was present in this apparatus only ½ per cent of nitrogen

Dr **McKesson** (U S A.) deplored the tendency of some manufacturers to diminish the standard of purity of the drug supplied in order to add to their profits, logical laboratory. There, however, are minor criticisms which do not detract from the general excellence of the book

---

PRACTICAL MICROSCOPY.

Third edition By F SHILLINGTON SCALES, M A , M D, B Ch Cantab , University Lecturer in Medical Radiology and Electrology, Cambridge London Baillière, Tindall and Cox 1926 Pp 332 8s 6d

THE third edition of this manual has been revised and brought up to date without, however, any extensive alterations to the size in scope of the volume The choice of an instrument, the structure and use of the various accessories, photomicrography, practical optics, and microscopic technique are dealt with simply and adequately , and Dr Scales's little book remains a safe and adequate guide to those beginning the study of microscopy

---

MANUAL OF DETERMINATIVE BACTERIOLOGY

Second edition By HENRY BERGEY, University of Pennsylvania Philadelphia, U S A Assisted by a Committee of the Society of American Bacteriologists Baltimore Williams and Wilkins Company, London Baillière Tindall and Cox 1925 Pp 462 25s

THE second edition of this now well-known manual of bacterial classification appears a little over a year after its original publication, and is in size and form but little altered, although some alterations have been made in the generic names for reasons of priority The chief noticeable changes in the manual are the correction of certain errors and the rectification of some defects which we pointed out when reviewing the first edition —notably the failure to include synonyms in the index, which formerly made it impossible for an organism to be traced by one who was not conversant with the system in use, and the lack of descriptive headlines to the pages, the introduction of which facilitates rapid reference Even so the book is not easy to find the way about in, and we would suggest that in a future edition a tabular statement might be inserted at the commencement showing the inter-relationships of the various orders, families, and tribes We notice that the page references in the short but important section which details the method of identifying an unknown organism from a knowledge of its characters (pp ix -xi.) are not always correctly given The nomenclature in use is often cumbersome, and lacking in attraction for the medical bacteriologist who deals with only a relatively few organisms and is concerned in his groups with minutiæ of differentiation which are of no interest to botanists and commercial bacteriologists This tends to make him intolerant of the involved and laborious terminology which is here presented, but he must realise, and the perusal of recent literature makes it evident that he is beginning to realise, that a more exact classification is desirable than one which includes the influenza organism, the diphtheria bacillus, and the tetanus organism in the same genus For this reason Bergey s manual must be welcomed, and even if the classification of the Society of American Bacteriologists does not survive in its entirety there is no doubt that it marks an important stage in the history of this branch of biological study

MESENTERIC VASCULAR OCCLUSION

By H J COKKINIS, M B B S , F R C S Surgical Registrar, London Lock Hospital London Baillière, Tindall and Cox 1926 Pp 159 10s 6d

THIS is a monograph on what is usually regarded as a very rare disease of which the author has been able to collect 76 hitherto unpublished cases The anatomy of the blood-supply of the intestine is described and experiments to show the effect of occlusion of vessels brought forward The clinical findings consistently agree with the results of these experiments There follow a useful description of symptoms and guides to the diagnosis and treatment The book forms a definite contribution to the subject.

A VILLAGE ON THE THAMES

Whitchurch, Yesterday and To-day By Sir RICKMAN GODLEE Bart , K C V O , M S , F R C S. With a Memorial Sketch by Sir GEORGE NEWMAN, K C B , and a Foreword by Lady GODLEE. London George Allen and Unwin, Ltd 1926. Pp 283 7s 6d

A SIDE of Sir Rickman Godlee's life well known to a large circle of friends though little revealed in his scientific and biographical writings is illustrated by this study of the history, local and natural, of Whitchurch, where his charming country house Coombe End Farm, was situated The book is not a detailed story of the village such as finds its way into weighty county histories—in respect of Whitchurch much of this work had been previously done by Canon Slatter, who is frequently cited by Sir Rickman Godlee. Part of the volume appeared in short chapters in the parish magazine at the invitation of the incumbent, and these, especially the earlier sections bear the imprint of their intended audience; but the author's wide knowledge of natural history and far-ranging if desultory antiquarian studies have carried him beyond his original design, with the result that we obtain from him résumés of subjects which often form the basis of learned discussions and sometimes of legal interpositions He deals, indeed with all sorts of historical and geological points as they are illustrated by the site and soil of the angle in the Thames Valley represented by Whitchurch and Pangbourne. In the chapters entitled "Our Mammals," "Some of Our Birds," "Beneficent Birds," and "The Gamekeepers' Larder" he appears as a field naturalist of high order with a large range of exact knowledge under which to classify his observations, and on page after page familiarity with what may be called rural phenomena is apparent. Interesting chapters deal with the rectors of Whitchurch, Whitchurch bridge, and the names of the various meadows, lanes, and pits in the village and vicinity. The study of place names "is frightfully difficult but so absorbing that some people devote their whole lives to it," says the author, but the study has the greatest importance in local history because of the relative permanence of such names even though their origins and significance seem impossible to trace

We recommend this unpretending volume to all country dwellers Certain of the charming illustrations are reproduced from water-colour sketches by Lady Godlee, others are from aquatints by Joseph Farington, who executed a whole series of Thames views, and one of the most effective, "The Thames in Flood," is from a water-colour drawing by the author himself

---

JOURNALS

GUY'S HOSPITAL REPORTS No 2. April, 1926 (Vol VI , Fourth Series) —"A F H" contributes an obituary of George Herbert Hunt This is followed by a paper on heart disease and pregnancy by Hunt, edited by J M H Campbell, in which, as a result of work carried out in the five years before his death, Hunt concludes that provided the heart is not enlarged patients with mitral disease stand pregnancy well , if the heart is enlarged the risk is greater and very similar whatever the valvular lesion present, while in auricular fibrillation the result of pregnancy is disastrous —G W. Rake describes a case of annular muscular hypertrophy of the œsophagus and discusses the findings —W E Tanner gives an account of a case of dysphagia due to a posterior pharyngo-œsophageal pouch —The association of chronic duodenal ileus with gastric and duodenal ulcers is the subject of a series of papers A F Hurst had previously shown that the presence of chronic duodenal ileus would predispose to ulcers in this region, and

Reviews and Notices of Books.

EUGENICS

The Need for Eugenic Reform By LEONARD DARWIN London John Murray 1926 Pp 529 12*s*

THE object which the president of the Eugenics Education Society has had in writing this book is not, we take it, so much to advance any particular views which he may hold himself as to persuade ordinary educated men and women that they must take racial problems seriously and give time and attention to the eugenic method of attempting to improve mankind It is well adapted to this purpose Among a great deal of writing on the subject which shows more enthusiasm than common sense, or is frankly propagandist in aim, Major Darwin's survey is conspicuously sober, sensible, and sincere The subject is full of difficulties, of which the outstanding ones are that we know very little of the genetical structure of individuals (though experience has taught us something of mass inheritance) and that we are not sure what we are aiming at From this uncertainty it necessarily follows that the author, where he does take a definite line, is sure to be provocative to someone Take, for example, his summary (p 327) "Almost every class must on balance be receiving additions from below, and must in consequence be suffering from the inferior quality of its recruits In short, as far as we can judge from the facts at our disposal, the nation as a whole is slowly and steadily deteriorating as regards its average inborn qualities" It would be difficult to imagine propositions of a more debatable kind or of a higher sociological importance We hardly think that he really expects to convince us of their truth What is needed is that we should think about them earnestly and his book forms an admirable introduction to the closer study which they deserve from everyone who takes part in public life Of his constructive proposals no one realises the difficulties more than Major Darwin At some of them it is possible to laugh, which is unfortunate, in so far as it may encourage those who believe that eugenics is unnecessary and that man is still sufficiently an animal to adapt his effective multiplication to his circumstances without much deliberate thought

BASAL METABOLISM IN HEALTH AND DISEASE

By EUGENE F DUBOIS, M D, Medical Director, Russel Sage Institute of Pathology Associate Professor of Medicine, Cornell University Medical College Philadelphia and New York Lea and Febiger 1924 Pp 372

Dr Eugene DuBois has probably done more work on the subject of basal metabolism in disease in recent years than any other man, and his book therefore ranks as an authoritative presentation of the subject The first half of the volume deals with physiology, the methods used in measuring, and the standards on which the normal basal metabolism is assessed Dr DuBois quite rightly points out that in the Tissot and the Douglas bag method of measuring respiratory exchange the volume of the inspired air is greater than the expired air, so that the oxygen intake cannot merely be obtained by subtracting one percentage of oxygen from another, and multiplying by the pulmonary ventilation and dividing by 100 He might well have explained how by calculation these errors can be obviated The lack of insistence on this possible source of error in recent monographs suggests that this error is not corrected in some of the work carried out at the present day by this method

The other half of the book contains an account of metabolism in disease wisely enough not confined to basal metabolism. He also considers observations made on the increased respiratory exchange after the intake of *foodstuffs*, a subject that may be of importance in explaining the cause of obesity A chapter on metabolism in fever is of special interest and, needless to say, the metabolism in thyroid disease is very fully considered The subject of diabetes is also treated from a wider aspect than merely that of the basal metabolism, this section is a particularly valuable one, though it is a pity that the author does not state more definitely whether he believes that the low respiratory quotients so often obtained are, or are not due to a conversion of fat into carbohydrate The evidence, though not conclusive, appears to favour the former view

The description of the various standards of comparison is particularly useful Dr DuBois is inclined to believe that the metabolism is proportional to the surface area in normal individuals It is surprising to find him applying the same law to such frankly abnormal subjects as the obese He quotes with approval Means's observations that in this condition because the metabolism is proportional to the body surface the body metabolism in the obese is unaltered But is it right to apply the body surface law at all to such a condition? Would not the covering of fat be expected to diminish the loss of heat? Again, the extra weight of the individual is due to fat Is there any evidence that the number of cells in the body is increased in this condition? In any case the metabolism of mere adipose tissue must be extremely low To us it would seem that Means's result is a proof that the metabolism in obesity is abnormal—i e, much higher than would be expected—and that in these cases it can be explained by a luxus consumption following on an excessive food intake Of course such a view does not apply to cases of obesity which are of endocrine origin and in some of these cases there is no doubt that the metabolism is low It would seem desirable to regard patients as physiological units and to use as a standard the metabolism calculated from the predicted weight of the individual, or the weight of the patient before he became fat

HISTOLOGICAL TECHNIQUE

By H M CARLETON, M A, B Sc, D Phil, University Lecturer in Histology, Oxford Chapters VII and VIII in collaboration with FREDERIC HAYNES, B A, Demonstrator of Histology Oxford University Press, Humphrey Milford 1926 Pp 398 16s

PRACTICAL text-books can never replace the actual experience of the laboratory, but such manuals must always be necessary unless science is to be bound by oral tradition With the help of the written word the tyro may postpone, even indefinitely, the moment when the patience of his teacher becomes exhausted, and the expert is glad from time to time to refresh his memory Dr Carleton's book will prove both a safe guide for the beginner and a valuable companion for the more experienced worker It is essentially practical and is full of just those useful tips which make all the difference between complete success and mediocrity in this exacting science

The first part deals with the cell as a structural unit and a physico-chemical entity, and outlines the methods employed in histology Part 2 treats of histological methods in detail Part 3 describes the accessory methods in use—dark-ground illumination, histo-chemical tests, injection methods, and vital staining In Part 4 the methods for special organs and tissues are described, and in Part 5 the technique of morbid histology, bacteriology, and parasitology

In a book of this size it is obviously impossible to include everything, many methods and modifications of methods must necessarily be omitted We should have been glad to see more emphasis laid on the value of carbon bisulphide as a clearing agent, or butyl alcohol as recommended by F W Twort, and those extremely useful decalcifying agents, Perényis' and Jenkins's fluids might well have been included The small Cambridge rocker and the humble razor receive scant recognition, nevertheless, with these an amount of first-rate material can be dealt with which would astonish the inhabitants of an ordinary histo-

MATERNITY AND CHILD WELFARE.

CONFERENCE AT WESTMINSTER

THE Fourth English-speaking Conference on Maternity and Child Welfare was held at the Caxton Hall, Westminster, from July 5th to 8th, and over 700 delegates attended Sir Kingsley Wood (Parliamentary Secretary to the Ministry of Health) acted as President in the unavoidable absence of Mr Neville Chamberlain

In his presidential address Sir Kingsley Wood emphasised the need for complete cooperation between voluntary societies and the statutory health authorities He referred to the slight set-back which there had been during the last two years in the decline of the infant mortality-rate, and to the high rates still prevalent for still-births and maternal mortality More effectual antenatal supervision and more maternity hospital beds were needed, though progress in these directions had been made during the last two years Seventy per cent of the rural population were now provided with trained midwives, and he hoped that the Midwives and Maternity Homes Bill, when it came into operation, would raise the standard of maternity homes The Ministry of Health hoped to do something in the near future to promote better housing in the villages and rural districts But it needed the backing of public opinion, and congresses such as the present one were the best means of educating the public

The Well-being of Children from One to Five Years Old

At the first session Dame Janet Campbell (Ministry of Health) opened a discussion on this subject There was, she said, a gap in medical supervision between infancy and school entrance which was not being filled The child at this age was particularly vulnerable to the onset of disease It was liable to develop digestive and nutritional disorders, respiratory, aural and nasal affections, squint, the infectious fevers and all the sequelæ which occurred after such diseases as measles, whooping-cough or acute anterior poliomyelitis The best means of reducing this incidence were (1) better education of mothers in the management of the ex-baby, (2) periodical skilled supervision, and (3) facilities for early treatment Competent health visiting would probably do more than anything else to raise the standard of health of the pre-school child Special sessions should be held at the infant welfare centres for ex-babies, facilities for treatment at the school clinics should be extended to the children under 5, and better provision should be made for the adequate nursing of infectious diseases Modern methods of immunisation ought to be considered in the case of diphtheria and scarlet fever, and orthopædic treatment ought to be arranged for in cases of tuberculosis, infantile paralysis, rickets, and the like

Miss W B Ireland (New York) quoted the remarks of a health official to the effect that, although the need for pre-school work was realised, they had first to reach a greater percentage of the infants, to secure better supervision of school children, and to carry out an intensive antenatal programme

Prof de Buys (Tuluana University, New Orleans) said that the infant should come under the care of the pædiatrician from the moment of birth, and described the arrangements which were made in a New Orleans maternity hospital Practically all the babies, he said, were breast-fed, and in order to prevent the initial loss of weight, they were supplied with the milk of other mothers during the first few days Great care was given to the preparation of the breast, and there had been no case of fissured nipples or abscess of the breast during five years Puerperal pyrexia, he said, was never due to the breasts if the axillary glands were not enlarged Mother and infant were usually discharged at the eleventh day, though occasionally the infant was kept in longer All babies were brought up for examination at the end of the fourth week, and there was a regular follow-up system This supervision from the beginning was essential for the study of birth injuries and the diseases and tendencies of the very young child

An animated discussion followed, in the course of which it was remarked that it was easy enough to get the ex-baby to the centre, but very difficult to get him fed properly Health visitors, it was suggested, needed more knowledge of cooking and how to lay out the housekeeping money, and regret was expressed that the free milk-supply had dwindled away

The Crippling Diseases of Childhood

At the second session Dr F J Poynton (London) described the present want of knowledge concerning the prevention of rheumatic heart disease in childhood Acute rheumatism under the age of 5, he said, had not really been investigated In children acute rheumatism was largely a town disease Amongst other factors he thought that scarlet fever, measles, and diphtheria might predispose to it, but he was doubtful whether diet had any definite influence The part played by streptococci in the ætiology required investigation, and more complete knowledge about the school conditions which gave rise to rheumatism was wanted The damaged heart of a child, said Dr. Poynton, needed coaxing forward, and its treatment should not be the same as that given to the damaged heart of an old person He sounded a note of warning against the formation of numerous special heart clinics

Dr G R Girdlestone (Wingfield Orthopædic Hospital) dealt with other forms of crippling and insisted on the supreme value of early discovery and prompt treatment The discovery that something was going wrong must be made while the child was still like other children Those in charge of children must be on the look-out for limps, they must take the child to the orthopædic clinic at once In tuberculous cases the tuberculosis officers had power to arrange for payment The danger of infection from properly treated surgical tuberculosis was nil In infantile paralysis much good could be done if the child was taken into hospital at the earliest possible stage of the acute disease

During the discussion congratulations were accorded to Dame Agnes Hunt on the recognition of her work in inaugurating the movement for the salving of cripples The need for unity of effort and better cooperation between all the organisations working for child welfare was ably voiced by Miss Margaret Beavan (Liverpool Child Welfare Association)

The Father's Part in Child Welfare

On the second day Dr James Fenton aroused much interest by his description of the Father's Council, organised in connexion with the welfare centre at Lancaster-road, Kensington Many of the subsequent speakers expressed their intention of organising similar councils in their districts

The value of light treatment was discussed by Dr C W Saleeby, Dr Stella Churchill, Dr Stanley Banks, and Sir Leslie McKenzie

Speakers at the afternoon session, which was devoted to publicity methods, included Lord Riddell. and Dr J. E Sandilands (Bombay) Mr. Sydney Walton (Harrow) urged that each hospital should have its information committee or company of torch-bearers Hospitals should be lighthouses as well as lifeboats Reports should be humanised and they should not be written in officialese, and committees should find out local residents who could write attractively A mother's bookshop ought to be established in every large centre of population, and attractive leaflets distributed from door to door The New York Metropolitan Insurance Co, said Mr Walton, issued model leaflets

Midwifery in the Homes of the People

On the third morning a joint session with the Royal Sanitary Institute to discuss this subject attracted a large audience The points of view of the midwife the district nurse-midwife, the consultant, the medical this receives ample confirmation from the cases here published by A F. Hurst and P J Briggs, R P Rowlands, J Gaymer Jones, and J A Ryle —The correct treatment of acute obstruction of the small intestine is the subject of a paper by R P Rowlands, who discusses the need for early diagnosis and describes a temporary valvular enterostomy as the operation of choice in this condition —A case of chronic volvulus of the pelvic colon simulating pyloric obstruction radiologically diagnosed and successfully resected is described by A F Hurst — Seven cases of ball-valve accumulations in the rectum form the subject of a paper by J A Ryle, who discusses the causes, symptoms, diagnosis, and treatment of this condition —F A Knott contributes a short study on the use of salicylates in gall-bladder disease He finds as a result of animal experiments that the average concentration of sodium salicylate in the bile after oral administration in pharmacopœial doses of any of the ordinary compounds is very small as compared with the minimum concentration necessary to obtain bactericidal effects in the biliary tracts — Two cases of secondary sarcomatous deposits in the brain are described in detail by J G Weston —G W Nicholson continues his studies on tumour formation, dealing in this part of his paper with ectopic endometrial tumours He gives an account of the nomenclature and histology of the condition and discusses the pathology, classification, and origin of these tumours, giving a broad summary of the literature

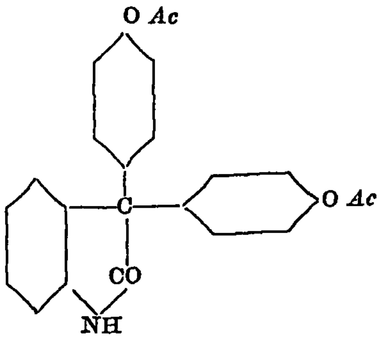
The Cancer Review —A Journal of Abstracts Bristol. John Wright and Sons Subscription 30s per annum —This is the first number of a new journal issued under the direction of the British Empire Cancer Campaign and having as its object the publication of abstracts and reviews of current contributions to the literature on cancer The journal will appear in ten numbers during the year It is under the editorial control of a committee composed of Dr F Cavers, the General Editor, Dr W. Cramer, Dr C E Dukes, Prof H Shaw Dunn, Dr H J B Fry, Dr M Greenwood, Dr. E L Kennaway, Dr P J Kerley, and Prof C A Pannett The members of the Editorial Committee have been responsible for the abstracts, which number over 100 The abstracts are conveniently grouped under five headings (1) General, (2) experimental and biochemical, (3) clinical and pathological, (4) radiological, (5) statistical An author's index is also provided The abstracts are full, clear, and critical The literature on cancer is overburdened with statements based on little or no reliable evidence, and if the journal succeeds in giving a critical reflection of current work on cancer it will fulfil a useful purpose

Reports and Analytical Records.

ISACEN ROCHE BRAND

(Hoffmann-La Roche Chemical Works, Ltd, 7–8 Idol-lane, London, E C 3)

Isacen, which is described as a new synthetic non-toxic purgative, is diacetyldihydroxyphenylisatine which has the structural formula



This compound is a white powder melting at 242° C It is saponified by alkalis with the formation of dihydroxyphenylisatine In consequence of its insolubility in water and dilute hydrochloric acid "Isacen" passes through the stomach unchanged In the alkaline medium of the intestine the acetyl groups are slowly broken off and dihydroxyphenylisatine liberated, which can then exercise its specific action on the colon

When submitted to analysis the tablets of "Isacen" gave the following results —

Average weight of each tablet	3/5	gr
Isacen contained in each tablet	1/13	,,
Petroleum ether extract	0 44	per cent
Alcohol extract ("Isacen," m pt 242° C)	12 60	,,
Water extract (dextrin, &c)	37 80	,,
Filling (wheat starch)	49 16	,,

On saponification with alkali the correct amount of acetic acid is liberated

VITALIA MEAT JUICE (LIQ HÆMOGLOBIN DULC)

(Vitalia Limited, 17a, Boniface Street, Westminster Bridge Road, London, S E 1)

We have previously noticed this preparation of British origin, which according to the published analysis contains water, 81 70 per cent, total ash, 1 07 per cent, sodium chloride, equivalent to chlorine, 0 25 per cent, total phosphoric acid, 0 05 per cent, total nitrogen, 2 50 per cent, hæmoglobin, 8 00 per cent The percentage of hæmoglobin is, of course, a point in its favour, and as it is produced by a cold process the natural vitamin content is preserved Meat juice is a convenient form of nutriment in many conditions, especially where a rapidly acting tonic is indicated, and this particular preparation has been found valuable, the assimilable sustenance inducing sleep where the patient is liable to awake after short periods In the exhaustion after severe operations and illnesses it can be easily digested by the weakened subject Vitalia meat juice is palatable and is put up in bottles of 1, 2, 4, 8, and 16 ounces The dose is one to two teaspoonfuls for an adult, half a teaspoonful for children, and 5 to 15 drops for infants It should be diluted with four times as much cold water or milk and taken three times a day, or more frequently in severe illness

ANGOSTURA BITTERS

Messrs Henderson and Co, the consignees of the preparation "Carypton and Angostura Bitters" noticed in our columns on June 26th last, complain that we have fallen into the serious error of stating that Angostura bitters "are commonly supposed to be compounded of Angostura bark (cusparia)" The authority for the belief will be found in Thorpe's Dictionary, article Cusparia Bark, written by Prof Barger, and the B P Codex (1907, page 303), article on Cusparia There is no characteristic test known to chemists which will detect small quantities of the constituents of Angostura bark which Messrs Henderson say is not one of the contents of Carypton and Angostura bitters That product they state to be named after the town of Angostura in Venezuela The satisfactory result, however, on analysis would appear to be the really important thing and not whether the bitter properties were obtained from cusparia or whether the popular name is a place name We accept the statement, of course, that the name "Carypton and Angostura Bitters" has a geographical and not a botanical significance

officer of health, the general practitioner, and the health visitor were described by selected speakers

Miss Doubleday (Midwives' Institute) said that the midwife was capable of doing her own antenatal supervision and had great opportunities of educating both father and mother in their own home The public must be made to understand that antenatal work was part of midwifery and that it should not be paid for separately

Miss Fowler (Q V J I N) pointed out that suitable women were deterred from taking up midwifery by the fact that they had to compete with the so-called handy woman There was room for the handy woman as home help The Midwives' Institute wanted the aid of consultant gynæcologists for the practising midwives, and would like to see post-mortem examinations made in all cases of maternal death from childbirth

Dr. T. Watts Eden (London) enumerated the conditions necessary for safe confinement in the home, and pointed out that puerperal sepsis was actually less among extern than among intern cases in hospital practice

Dr. W Allen Daley (Hull) said that in some districts midwives did no antenatal work, and that in others there was antagonism between the midwives and the antenatal centres Midwife inspectors should be educators and not detectives Midwives must be paid more highly, but there must be no fee from the patient for antenatal work

Dr. E K Le Fleming (British Medical Association), speaking as a general practitioner, said that it was all right to jeer at the handy woman if an efficient substitute was to be had ; he could not conceive of a general practitioner preferring a handy woman to a properly trained and sensible midwife District nurses in the country could do the work of the antenatal clinic in the town Women did not like to go to a clinic, deserting their own doctor and nurse More hospital beds were needed, but they would be useless without proper means of transport

Miss Paterson (New Zealand) stated that in view of the high childbirth mortality in New Zealand, she had been investigating the midwifery service of the European countries with a low mortality In Denmark midwives attended all cases and called in specialists when required In Holland great attention was given to antenatal work

Dr Leon Jona (Melbourne) said that midwifery should be carried out by specialists only

Dr. Dickenson (New York) said that the midwife waited for Nature, whereas the doctor did not ; therefore the midwife's cases did better than the doctor's

Mrs Bernard James mentioned that there were now district nurse-midwives in every district in Buckinghamshire

The discussion, therefore, brought out a strong body of opinion that confinements should, as a rule, take place in the home, and that the desire for hospital confinements is chiefly due to the housing scarcity

The Churches and the Child

On the afternoon of the third day a debate on the Churches and the Child was held under the auspices of the National Council for the Unmarried Mother and Her Child During the discussion the speakers, who represented many religious beliefs—all laid stress on the importance of caring for the bodily and mental, as well as the spiritual, welfare of the mothers The rescue work of the Salvation Army was described by Commissioner Adelaide Cox

The Chief Rabbi said that in poor districts the Jewish infant mortality was only half the non-Jewish All Jewesses, he said, fed their children at the breast, there was no baby-farming among them and no use of patent foods " as good as mother's milk " There was a total absence of alcoholism among poor Jewesses all over the world

Mr. J H. Lidiard pleaded for an effort to house the people in such a way as to prevent the need for rescue work He described the efforts of Church Army Housing Ltd , which provided houses for tenants at reasonable rates by getting rid of the uneconomic portion of a new house This was done, he said, by securing donations or mortgages at 2½ per cent instead of 5 per cent For example, a house costing £600, by means of a donation of £300, could be let at the rental of a house costing £300 Such companies, he suggested, might be formed widely

The discussion made it clear that all over the world the churches are now taking more interest in hygiene The opinion was, however, expressed that a great deal more might be done by religious bodies to fight the " denial of children "

During the conference a number of round-table discussions took place Dr S G Moore (Huddersfield) showed that child welfare was a more profitable proposition than tuberculosis work, and was, in fact, the best method of preventing tuberculosis A discussion on whether welfare centres should give advice about birth control brought out the usual difference of opinion on this controversial subject Other round-table conferences dealt with the provision for mentally deficient children under the school age and the prevention of congenital syphilis There was also a lecture by Dr Saleeby, and one by Dr Douglas White (Eugenics Education Society) on the Consequences of Heredity and Environment in Child Welfare Many visits to child welfare institutions were made

SOCIETY OF MEDICAL OFFICERS OF HEALTH

Tonsils and Adenoids

The Maternity and Child Welfare Group held its annual meeting during the conference, at which it discussed Tonsils and Adenoids

Mr George Waugh (London) gave an interesting history of the evolution of the operation of tonsillar enucleation at the Hospital for Sick Children, Great Ormond-street When the operation was instituted some 20 years ago, he said, it was hoped that it would abolish gland surgery, ear discharges, and mastoid disease The harvest of results had not proved disappointing, and as the years went by more and more conditions had been added to the list of those cured or benefited by tonsillectomy These included dyspepsias, malnutrition, dyspnœa, croup, recurrent bronchitis, and broncho-pneumonia The operation had been found beneficial for diphtheria carriers and as a prelude to the repair of cleft palate Cases of cyclical vomiting and nephritis also improved after the removal of a tonsillar septic focus Carditis of rheumatic origin had not been tackled on a large enough scale in this country In toxic irritability of the heart the results had been disappointing when the removal of the tonsil was incomplete, but had improved after enucleation was adopted In some cases of anæmia the results were good, and where there were enlarged mediastinal glands and suspicious signs at the left apex enucleation of the tonsils might avert the threat of sanatorium life Eye diseases in connexion with ear and throat trouble had benefited There was no age limit, said Mr Waugh, for the removal of septic foci, and 1385 operations had been on patients under the age of 2 years , the range was from 3 weeks to 70 years The test of disease in the tonsils was not inspection but rather the question Can concurrent ailments be explained in any other way ? Unsuspected abscesses had been found in 3000 cases amongst 30,000 operated on Anyone could learn the technique of the enucleation operation in six months, though bad tonsillar surgery unfortunately abounded

Dr R C Clarke (Bristol) said that he thought that the tonsil was a useful organ until it was knocked out Catarrh should, if possible, be prevented by protecting children from carriers of infection, but he did not believe in the causes usually supposed to lower resistance to catarrh, such as wet feet and clothes, rickets, and diet The local resistance of the nasal mucous membrane was very low in infancy and much more might be done to protect the infant from infection

Dr H K Waller (London) read a paper on the early symptoms and signs of ill-health associated with tonsils and adenoids Nasal trouble, he said, often led to bottle-feeding because the baby was unable to get the milk out of the breast Herding in houses in the winter was a common cause of catarrh Infection conferred no immunity An excess of carbohydrate in the diet of the ex-baby was one predisposing cause

Dr Octavia Lewin (London) said that a more systematic effort should be made to keep the baby's nose clear and to prevent "nasal constipation"

The Services.

INDIAN MEDICAL SERVICE

Special Recruitment, 1926

The Secretary of State for India announces that a Committee will be held at the India Office in the near future for the selection of European candidates for direct appointment to permanent commissions in the Indian Medical Service on special terms which include a gratuity of £1000 after six years' service, or £2500 after 12 years' service, together with free return passage to any officer so appointed who no longer desires to remain in the Service Otherwise the terms will be as detailed below

Appointment —Conditions of Service

Candidates must be under 32 years of age at the time of application, and must possess qualifications registrable in Great Britain and Ireland under the Medical Acts now in force

Up to the present time Indian Medical Service officers have been employed both in civil and military departments of Government, and have been interchangeable between the two The practice as regards employment in the civil and military side of the Service has been as follows

At the beginning of his career an officer was employed on the military side, which has medical charge of the Indian Army If he remained in military employ he held a post on the staff of a station hospital, or a specialist post, or a post on the administrative staff of the army, promotion being on a time-scale up to the rank of lieutenant-colonel and by selection to the ranks of colonel and major-general He could, however, if he chose, apply, after two years' Indian military service, to be registered as a candidate for transfer to the civil side, from which appointments are made to civil surgeoncies, established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes and to the specialist services (for example, public health, bacteriological and research departments, and the professorships at the medical schools) Such transfers normally took place after about seven years' service in military employment

The Lee Commission has, however, recommended certain changes in the organisation of the medical services in India, and in view of their recommendations only military employment can be guaranteed to officers entering the Indian Medical Service at the present time It is, however, guaranteed that they will be eligible for civil employment under such conditions of service as may be made applicable to officers in future appointed to the Indian Medical Service as a result of decisions taken on the Lee Commission report

Private Practice —War Service

Executive medical officers in both civil and military employment may attend persons unconnected with Government service provided their duty admits of it Candidates are, however, informed that while serving on the military side the opportunities for private practice are not great

Service during the war as a medical or combatant officer or in a position usually filled by an officer, counts towards promotion and pension so long as the rights of officers who have entered by competition are not interfered with

Pay

The monthly rates of pay for European officers in the Service are as follows —

Rank and service in rank	Basic pay	Overseas pay		Year of total service
		If drawn in sterling	If drawn in rupees	
	Rs	£	Rs	
Lieut	500	—	150	First
		—	150	Second
		—	150	Third
Captain —				
1 During first three years' service as Captain	650	—	150	Fourth
		15	150	Fifth
		15	150	Sixth
2 With more than three and less than six years' service as Captain	750	25	250	Seventh
		25	250	Eighth
		25	250	Ninth
3 With more than six years' service as Captain	850	25	250	Tenth
		25	250	Eleventh
		30	300	Twelfth
Major —				
1 During first three years' service as Major	950	—	—	—
2 With more than three and less than six years service as Major	1100	—	—	—
3 With more than six years' service as Major	1250	30	300	Thirteenth and over
Lieut Colonel —				
1 Until completion of 23 years' total service	1500	—	—	—
2 During twenty fourth and twenty-fifth years' total service	1600	—	—	—
3 After completion of 25 years total service	1700	—	—	—
4 When selected for increased pay	1850	—	—	—

Note —Until the completion of 23 years' total service basic pay is regulated according to rank and service in rank (column 1) which, owing to the system of accelerated promotion, may be in advance of the time scale of promotion Overseas pay is regulated solely with reference to length of total service (column 5)

In addition to grades there are a number of appointments as colonels on Rs 2200 to Rs 2500, according to the appointment held, and as major-general on Rs 2750 The appointment of Director of Medical Services in India, carrying pay at Rs 3200 per mensem, may also be held by an officer of the Indian Medical Service

It may be pointed out to intending candidates that the initial rates of pay for the Indian Medical Service, as for all Government departments, are based on the assumption that the majority of newly appointed officers will be bachelors It is also the case that an officer, when junior, is liable to more frequent changes of station than later on in his service, and he may therefore be put to considerable expense for transfers if he has a family Officers, therefore, who join the Service, married, may have considerable difficulty in living within their pay during the first few years of their service

Extras · Outfit and Allowance

Extras —In addition to the above rates, officers in military employment, when in command or second-in-command of the larger station hospitals, receive special allowances On the civil side there are public health, bacteriological, research, and professional appointments carrying special enhanced rates Special rates of pay are attached to the administrative appointments open to officers in both branches of the Service

Officers on appointment will receive an outfit allowance of £50, subject to certain provisions as regards previous commissioned service in any branch of His Majesty's forces

Pensions

The rates of pensions are as follows —

Service	Rates per annum	Service	Rates per annum
After 17 years	£400	After 23 years	£620
" 18 "	430	" 24 "	660
" 19 "	460	" 25 "	700
" 20 "	500	" 26 "	750
" 21 "	540	" 27 "	800
" 22 "	580		

The above rates are subject to revision, upwards or downwards, to an extent not exceeding 20 per cent in all, on account of a rise or fall in the cost of living, as compared with the year 1919 A deduction of 4 per cent on this account has already been made A further revision may take place on July 1st, 1927, and every three years thereafter

There are additional pensions ranging from £125 to £350 per annum for officers who have held high administrative appointments as colonels or major-generals These pensions are not subject to the above reduction

Passages

Officers on appointment are when possible, provided with passage to India by transport When such accommodation is not available passage at the public expense is provided by private steamer, or passage allowance is granted if preferred The wives and families of officers who are married prior to the date of the officer's embarkation on first appointment to the Indian Medical Service will also be provided with free passage to India at the public expense under the same conditions as those applicable to the officers themselves

Indian Medical Service officers are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their career

Increased Cadre

The allowance for furlough has been increased to 25 per cent, and the cadre has been increased 2½ per cent for study leave, making a total of 27½ per cent There are special allowances for officers whilst on study leave

Further particulars can be obtained on application to the Secretary, Military Department, India Office, Whitehall, London, S W 1 Letters should be marked "Recruitment for I M S"

The King has approved the grading of the following officers in the Indian Medical Service —

Capts C MacD Nicol, D V O'Malley, L G Pearson, J H Barrett, T H Thomas, J Carrey, G H Fraser, and W. H Critien

Maj R G Shaw officiates as Consultant Dermatologist in India, Army Headquarters, vice Maj T H Scott on leave Capt F H Whyte has been appointed Specialist in Surgery, United Provinces District, vice Maj R C Clifford, vacated Capt E C Linton has been appointed to charge of Brigade Laboratory, Jhansi, vice Capt G. D Jameson, vacated On relief by Maj H L Batra, Capt E R Daboo, officiating Civil Surgeon, Sibsagar, acts as Civil Surgeon, Sadiya Frontier Tract Lt B S Nat has been appointed Specialist in Surgery, Waziristan District, vice Capt F H Whyte Capt R C Wats to be Deputy Director of Pathology, Waziristan District, vice Maj S S Sokhey Maj G L Duncan to be Deputy Director of Medical Service, Western Command, vice Maj H M Inman. Lt-Col A. H Proctor, Civil Surgeon, Darjeeling, acts as Surgeon Superintendent, Presidency General Hospital, Calcutta, vice Lt-Col E E Water Lt-Col C A Godson, Civil Surgeon, Hooghly, has been appointed to hold medical charge of Civil Station of Serampore Maj P F Gow, officiating Civil Surgeon, Murshidabad, has been transferred to Hooghly Capt B H Singh, Resident Medical Officer, Medical College Hospital, Calcutta, officiates for him as Civil Surgeon, Murshidabad The services of Capt S N Hayes, Professor of Operative Surgery, King Edward Medical College, Lahore, have been placed at the disposal of the Department of Education Lt-Col R Kelsall, Physician, General Hospital, Rangoon, has taken over the duties of Civil Surgeon, Rangoon East, vice Maj S H Middleton West, proceeding on leave Maj G G Jolly has been confirmed as Director of Public Health, Burma. Lt-Col F V V Beit, Medical Superintendent, Geneva Hospital, has been appointed Superintendent, Burma Medical School, vice Lt-Col Fuller Good, Civil Surgeon, Rangoon West Dr D N Hazra, Civil Surgeon, Bogra, has been transferred to Bihram, vice Maj J J A. Brached. Dr S N Bhattacharjee, Civil Surgeon, Malda, succeeds Dr D N Hazra at Bogra Lt E F Hottinger, Civil Surgeon, Mianwali, and Dr G McGuire, Civil Surgeon, Karnat, have been taken on cadre of Civil Surgeons in the Punjab Maj R E U Newman officiates as Assistant Director of Hygiene and Pathology, Western Command Col F H G Hutcheson, A D M S, U P District, has been promoted Maj-Gen

ROYAL NAVAL MEDICAL SERVICE

The following appointments are notified Surg-Comdrs. G Carlisle to the *Champion*, A I Sheldon to the *Excellent*; and W N L Cherry to the *Warspite*, addl, and as Fleet M O (from date of joining) Surg-Lt A G L Brown to the *Defiance*

W T Donovan, A B Stewart, and H L Duncan to be Surg-Lts

ROYAL ARMY MEDICAL CORPS

Maj-Gen Sir M H G Fell, late R A M C, to be Lt-Gen.

Maj-Gen J R McMunn, late R A M C, retires on retd pay

Capt. A R F Clarke retires, receiving a gratuity, and is granted the rank of Maj

Temp Capt E F W Buckell relinquishes his commn on account of ill-health, and is granted the rank of Capt

J D Borham to be temp Lt

ROYAL MILITIA OF THE ISLAND OF JERSEY

Light Infantry —Surg Lt-Col P B Bentlif is placed on the Res of Mila Off, and is granted the hon. rank of Surg-Col

TERRITORIAL ARMY

Lt-Col J H Hunter to be Bt Col

Maj (Prov) E M Douglas-Morris is confirmed in his rank

Capt H J D Smythe to be Maj

Capt A H Macklin, late R A M C, to be Lt and relinquishes the rank of Capt

Lt E G R Grant, late R War R, to be Lt

Lt W T B Joss, late North'd Fusrs, to be Lt

Supernumerary for Service with O T C —Capt. H. S Allen late the King's R, to be Lt. supernumerary for service with Medical Unit, London Univ, O T C, and relinquishes the rank of Capt

TERRITORIAL ARMY RESERVE OF OFFICERS

Capt R J McN Love, from Active List (supernumerary for service with Medical Unit, London University O T C), to be Capt

Lt E A Sparks, from Active List, to be Lt

WEST AFRICAN MEDICAL STAFF

Dr J Y Wood is promoted a Senior Medical Officer in Sierra Leone in succession to Dr J C Murphy, retired, Dr F Ross, a Senior Medical Officer in Nigeria, in succession to Dr C W McLeay, retired, and Dr L H Booth, a Senior Medical Officer in Sierra Leone, in the place of Dr A M Dowdall, who has been transferred to the Gold Coast in succession to Dr G J Keigwin, retired

---

The late Sir John Sherburn —After a somewhat prolonged illness Sir John Sherburn, who had retired from active practice, died at his home, Brantingham Thorpe, Brough, East Yorkshire, on July 7th Born in 1851, the son of the late Mr John Sherburn, of Howden, he studied at the University of Edinburgh, where he graduated in medicine in 1875 He became house surgeon and pathologist to the Hull Royal Infirmary, and then took up practice in Hull For a long time he was consulting surgeon to the Hull Royal Infirmary and he was intimately concerned with the foundation of the Hull Victoria Hospital for Sick Children He was sheriff of the city in 1886–7, entered the town council in 1887, and served two years as mayor, from 1888 to 1890 He was appointed a J P for Hull in 1889, and later for the County of the East Riding of Yorkshire, he was also Lieut-Colonel of the Northumbrian Brigade, R F A., and a representative member for the East Riding on the Territorial Force Association Sir John Sherburn several times attempted to enter Parliament in the Conservative interest, but he was never successful He was a partner in a large shipping firm at Hull and a vice-chairman of the Shipping Committee of Hull Chamber of Commerce He was knighted in 1902 In 1884 he married Louise Ainley, youngest daughter of the late William Bailey, J P, of Winstead Hall, Holderness Lady Sherburn survives him, with two sons and three daughters

PNEUMONIA CASES IN FEVER HOSPITALS

Practitioners are sometimes heard to grumble that the notification of diseases other than exanthemata may be of statistical value, but brings them no help in dealing with actual cases It is an old grievance, and every effort towards its removal gives an impetus to the slow growth of confidence in the administrators of public health, whose incessant demands for the filling up of forms involve labour which often seems to be unproductive The arrangements chronicled in the annual report[1] for 1925 of the Scottish Board of Health, whereby additional beds for cases of pneumonia are provided in city or county hospitals, will bring welcome relief to the doctor as well as to the patient s family The reasons for selecting pneumonia for special consideration are set out in the report The Board points out that far more public interest is devoted to tuberculosis, which accounts for some 4000 deaths in Scotland every year, than to pneumonia, though this disease claims an annual toll of 6000 to 7000 cases apart from those following measles or whooping-cough which are classified under the primary causes From these figures we cannot estimate the number of patients who suffer and recover from pneumonia in any year, since forms of the disease other than acute primary and acute influenzal pneumonia are not notifiable However, **Murray Leslie** and **J Browning Alexander**,[2] from a study of the literature, conclude that while wide variations exist, the average case death rate from pneumonia at all ages is about 20 per cent , on this basis there must be in Scotland at least 30,000 cases every year of some form of inflammation of the lungs—a condition which requires watchful care and expert nursing whatever the causative organism Moreover, though within the last 70 years the death-rate from most other diseases, including diseases of the respiratory system, has fallen, the death-rate from pneumonia in all its forms has increased greatly during this period It may well be that a number of affections formerly regarded as tuberculous or bronchitic are now diagnosed as pneumonia, and that the total number is also swelled by the inclusion of pneumonias which are really only terminal conditions, but when these possibilities are discounted, there remains a larger number of cases than can possibly be admitted to existing voluntary or Poor-law hospitals An obvious advantage of the scheme would seem to be the utilisation of empty beds during periods when infectious diseases proper are not prevalent The desirability of using the infectious disease hospitals to supplement the accommodation in voluntary and Poor law hospitals is recognised in the recent report of the Hospital Services (Scotland) Committee, though with anticipation that a big extension of the hospital work will fall on local authorities It has already caused a heavy strain on the hospital accommodation of some localities Glasgow, for instance, had 468 cases of pneumonia in its infectious diseases hospitals on Dec 2nd, 1925, the local authority having definitely undertaken to remove to its hospital any pneumonia patient whose doctor recommends his removal Aberdeen Burgh and Aberdeen County have given a similar undertaking, while several other local authorities are prepared to admit a varying number of cases of pneumonia to their fever hospitals Details of some of the schemes adopted for the institutional and nursing services for pneumonia patients are appended Of these the most informative is that of the Aberdeen Town Council, since the cases *admitted to the City Hospital* are divided into four groups and the death-rate is calculated separately The total number of cases *admitted to this hospital* in the period 1919 to 1925 inclusive was 896, of which 221 were primary lobar, 117 primary broncho pneumonia, 72 influenzal pneumonia, and 486 broncho pneumonia secondary to measles and whooping cough The case death-rates per cent were respectively 12, 38, 29, and 35 The figures are as yet too small to be anything but indicators, but the fact that lobar pneumonia has the smallest case death *rate* is significant The Aberdeen County Council are prepared to provide both a day and night nurse for grave cases treated at home if the patient is *unable to* bear the expense Hospital treatment is, however, regarded as the ideal to be aimed at, and in view of the easy and comfortable *methods of transport* now available, it is deemed safe to remove to hospital a patient suffering from pneumonia—except in the presence of signs of cardiac embarrassment—up to and including the fourth day of illness This clause would seem to refer to cases of lobar pneumonia where a crisis is to be anticipated, though this is not stated, and supplies an instance of the confusion in terminology referred to below. The total number of cases admitted to the Glasgow Corporation's fever hospitals in the same seven years was 12,517 The deaths among 5334 children under 5 years of age admitted with acute primary and influenzal pneumonia were 1404, representing a case death-rate of 26 3 per cent, while those among persons over five years—the large proportion of whom were young people—were 1323, a case death-rate of 18 4 per cent These figures take no account of the large number of cases of secondary pneumonias to which are admitted to measles and whooping-cough wards. No comment is made in the report on the fact that the case death-rate of cases under institutional care is not appreciably less than the estimated average for all cases The object of increasing largely the number of beds available for pneumonia patients is presumably not only to save life, but to reduce the period of convalescence and lessen the danger of relapses or sequelæ If the scheme is also to serve a scientific purpose, it will be necessary to arrange for a uniform classification of the cases admitted, since the term pneumonia, as loosely used in the report, covers many widely different conditions For the most part, the term appears to denote any sort of inflammation of the lungs, irrespective of the causative organism , elsewhere it seems to be used in a much more limited sense For example, the paragraph on Methods of Treatment (p 91) begins "A serum is now available for the treatment of about a third of all cases of pneumonia—viz , those due to the pneumococcus of Type 1 ' The last-named type certainly is not found in a third of "all cases of pneumonia," though it may account for a third of the cases of lobar pneumonia The nomenclature of this complex subject appears urgently to need revision

In drawing special attention to the measures taken to combat pneumonia in Scotland, we would not seem to imply that progress in the development of other public health measures is less noteworthy All sections of the report addressed by the Scottish Board of Health to its president, Sir JOHN GILMOUR, will repay study The 20 pages allotted to venereal diseases provide a summary of the pathology, sociology, symptoms, and successful modern treatment of these diseases, which is more informative than many large text books on the subject The section on housing is less encouraging Whatever opinion may be held as to the reasons for the failure to complete houses, it is regrettable to record that though 20,000 houses per annum are stated to be required, it has not been found possible to complete within a year 9808 houses which had actually been begun at the beginning of the year Closely allied to the housing problem are the concerted scientific investigations on rickets being carried out in Glasgow and elsewhere Significant conclusions drawn from a survey of data collected are (1) that rickets, though showing some signs of decline, is still a very widespread disease, (2) that the methods of diagnosis of early rickets are steadily improving in technique, and (3) that, as the result of extended experimental and clinical investigation, the methods of arresting and curing rickets are sufficiently developed and definite to justify the hope that the disease will now steadily and rapidly disappear No less energy is being shown in the attack on other problems of State medicine in Scotland, and the report gives promise that its successors will record changes and developments in many useful directions

THE BRITISH EMPIRE CANCER CAMPAIGN

THE Duke of YORK presided over the third annual general meeting of the British Empire Cancer Campaign on Monday, July 12th The Campaign, he said, had been initiated to link up research institutions and workers in the Empire, and the annual report showed that the founder's aims were bearing fruit He hoped that the *Cancer Review* (which we notice on p 128) would be useful not only to workers in the great research centres throughout the world but also to those in various branches of medicine who might wish to turn their attention to this line of study No opportunity should be lost, he pointed out, of affording all possible help to those independent research workers who might only be able to devote part of their professional time thereto, thus enabling them to follow their own individual lines of research The counties were now trying to take their full share by setting up their own centres or by county committees working in aid of the Central Fund, and he congratulated the Yorkshire Council on having already raised locally nearly £100,000, and on having taken steps to start the work of their research centre in connexion with the University of Leeds

His Royal Highness in his address presented ably the main features of a full year's work of the Campaign, and the annual report, which was made public immediately after, gives the details of the various researches and activities which have been supported financially and otherwise by the movement Among these may be mentioned maintenance grants to the Cancer Hospital, Middlesex Hospital, St Mark's Hospital, and St Bartholomew's Hospital, while to certain of these as well as to the London Association of the Medical Women's Federation radium is being allocated which was purchased by the Campaign with the assistance of the Medical Research Council The résumés of the work at the various centres selected for support appear in the document, and will be read with interest as showing the numerous and differing angles from which the various problems are being attacked Here lies the real hope, for those who are best able to endorse the optimism of the Minister of Health in respect of an approaching control of cancer are those to whom experience in scientific investigation has shown that no one solution of a particular difficulty is likely to effect much by itself, although its influence over other inquiries may be of superlative value At any time in the wide range of experiment now engaged upon an inference may turn itself into an indication, and an indication into a revelation, for which reason it is justifiable to be sanguine, even while it is very necessary to be on our guard against premature conclusions

A paper by Dr THOMAS LUMSDEN published this week in THE LANCET is an excellent example of the kind of large yet intensive research which the Campaign is prepared to support Dr LUMSDEN's work at the Lister Institute has been subsidised in an open-handed manner by the Campaign, and we believe that those who study his paper sufficiently closely to be able to follow the conclusions will agree that these are of real moment The hope of the discovery of an efficient antiserum against sarcoma, which can be employed in the human subject with safety, may seem too good to be true, but imagination has made freer excursions with less support and without disappointment

◆

PYORRHŒA AND THE MECHANISM OF TOOTH ERUPTION

THE mechanism of normal tooth eruption, though apparently simple, is not yet understood Of the many theories put forward to explain the process none is completely satisfactory. Recent work by an Austrian observer, Dr B GOTTLIEB, summarised in the *British Dental Journal* of May 1st by Mr A T PITTS, is of interest not only because Dr GOTTLIEB's views are original, but also because he founds on these views an entirely new conception of the nature of the pathological changes occurring in pyorrhœa In order to understand his argument it is necessary briefly to recall what is generally accepted as the sequence of events in the eruption of a tooth. Previous to eruption the developing tooth is surrounded by a fibrous capsule known as the dental follicle It has been shown by HERTWIG, VON BRUNN, and others that this follicle contains an abundance of epithelial cells derived by buddings off from the enamel organ, which form a more or less complete investment round the tooth known as the sheath of Hertwig The dental follicle is in contact with the enamel of the crown but not adherent to it, except that at some stage previous to eruption the epithelial cells go to form part of that transparent pellicle external to the enamel which is called Nasmyth's membrane In the root part of the tooth the dental follicle is adherent to the cement covering the dentine of the root and in this situation is called the periodontal membrane or periosteum of the tooth Just about the time of eruption, though exactly when is not known, the epithelial cells in the coronal part of the follicle become detached from the follicle and blend with the epithelial remains of the enamel organ to form Nasmyth's membrane When a tooth commences to erupt it has usually been supposed that the cleavage of these cells has already extended as far as the neck of the tooth, so that there is a space extending to the neck where the periodontal membrane commences. It has further been supposed that either by an advancement of the tooth through the bone or by an absorption of the gum, or both combined, this deep space or trough round the crown undergoes a progressive shrinkage until when the tooth has completed eruption there is a narrow collar of gum surrounding the neck of the tooth This collar is lined with epithelium which at its base blends with the periodontal membrane and may even be continuous with Nasmyth's membrane on the enamel. So far Gottlieb seems to agree with the current views, but the post-eruptive changes as described by him introduce an entirely new conception. Gottlieb believes that when a tooth erupts, the base of the gingival trough, as the space round the tooth is termed, is not situated at the junction of enamel and cement, but is attached to the enamel at some distance from the neck, and that even when a tooth has completely erupted in a clinical sense the actual base of the gingival trough is still above the level of the enamel-cement junction. The process of eruption according to Gottlieb involves a gradual separation of the epithelium from the enamel so that the base of the gingival trough progressively travels towards the root. Concurrently with this cleavage of epithelium there is a proliferation of epithelium towards the root. But even when clinical eruption is complete the process still goes on, for as the base of the gingival trough approaches the neck of the tooth the epithelium proliferates into the periodontal membrane and eventually the denudation of the tooth may not stop short at complete exposure of the crown as commonly supposed, but may even go on until a portion of the root may become visible as part of a purely physiological process. This final stage of eruption does not go on indefinitely, though Gottlieb does not indicate the stage when eruption is complete. Concurrently with these progressive changes in the soft tissues at the neck of the tooth there is also a progressive absorption of the level of the alveolar margins which keeps pace with the detachment of epithelium from the enamel. According to Gottlieb this alveolar absorption occurs early, even before there is any down growth of epithelium into the periodontal membrane. Thus, to summarise, eruption as Gottlieb understands it comprises a threefold process (*a*) detachment of epithelium from the enamel, (*b*) absorption of the alveolar border, and (*c*) proliferation of epithelium at the base of the gingival trough towards and eventually into the periodontal membrane. These processes should occur harmoniously and represent a physiological process without any pathological significance. This point of view would imply that eruption is a much lengthier process than previous observers have imagined, continuing, indeed, long after a tooth has advanced into occlusion with its antagonist. Moreover, under Gottlieb's hypothesis, the denudation of the gum from the root of the tooth instead of being a pathological process, as it is generally assumed to be, would be the final stage of normal eruption. It would be easy to criticise this theory, but there are certain facts which support it, and it cannot be lightly put on one side, especially since it seems to help us to elucidate the pathology of pyorrhœa.

Gottlieb recognises three forms of pyorrhœa. Dirt pyorrhœa, paradental pyorrhœa, and alveolar atrophy. In the first two the changes are essentially those occurring in eruption, but they occur in a disorderly fashion instead of harmoniously. In dirt pyorrhœa the initial factor is some local irritant such as food stagnation, faulty fillings or crowns, and crowding of teeth. This stagnation leads to inflammatory changes in the gum. In normal eruption the gum shrinks as the epithelium grows along the root, and the gingival trough is preserved at a stable depth. In dirt pyorrhœa the inflammation prevents this shrinkage and leads to hypertrophy. The gingival trough thus becomes abnormally deep in fact becomes a pocket. The inflammation may cause a rapid proliferation of epithelium towards the root. At first the epithelial lining of the pocket may be intact, but it soon becomes destroyed in part or wholly, by ulceration, and a pus pocket results. The spreading inflammation then destroys the fibres of the periodontal membrane, which is thus stripped from the cement of the root. In paradental pyorrhœa the chief factor seems to be an uneven shifting of the base of the gingival trough, the proliferation of epithelium being asymmetrical. The normal defensive power of the trough in resisting infection is weakened and inflammation results, tartar and food being deposited with resulting bacterial stagnation. The ætiology of paradental pyorrhœa is still obscure, for it may occur in healthy mouths and without any apparent stagnation.

Two forms of bone destruction are described by Dr Gottlieb—marginal atrophy and diffuse atrophy. The former is part of the mechanism of normal eruption and becomes pathological only when it does not occur evenly round the circumference of the tooth. This is comparable to the uneven detachment of epithelium in paradental pyorrhœa. Marginal atrophy occurs chiefly in dirt pyorrhœa and is caused by the same factors of local irritation as lead to the deepening of the pocket in that condition. Diffuse alveolar atrophy is an entirely different condition. It occurs in a lateral plane leading to widening of the periodontal space, whereas marginal atrophy occurs in a vertical plane. Diffuse atrophy may affect any part of the alveolar bone and may occur without any lesion of the gingival margins. This is an important distinction, for Gottlieb believes that it may occur as a primary lesion and not as an extension of marginal infection. Since the stability of a tooth depends on the bone being intact, it follows that a destruction of bone laterally in any part of the socket must lead to loosening of the tooth. The diagnosis of the condition depends on a recognition of this fact. If a pocket is shallow compared to the degree of loosening, then the condition is primarily one of diffuse alveolar atrophy. If the pocket is deep, then the loosening is due to vertical destruction of bone—i e, to dirt pyorrhœa. Diffuse alveolar atrophy is often, though not invariably, associated with paradental pyorrhœa, though Dr Gottlieb does not consider that they have a common ætiology. Those who are interested in his views will find them well set out in a monograph published by him in Vienna last year.[1] Gottlieb does not discuss in this book the morbid histology of diffuse atrophy, but it is evident that the primary change must be in the periodontal membrane and that the condition must be essentially one of bone absorption and its replacement by fibrous tissue. H K Box,[2] who describes a similar condition in his valuable studies on periodontal infections, has given an elaborate account of the morbid anatomy of what is apparently the same condition. The name given by him to the condition is rarefying pericementitis fibrosa. It is a process of bone absorption both by halisteresis and lacunar absorption, and replacement of the bone absorbed by a low grade of fibrous tissue. Like Gottlieb, Box lays stress on the fact that it may occur as a primary lesion and that it leads to loosening of the teeth. There are further parallels between the work of the two observers. Both describe the down-growth of epithelium into the pockets. Box, however, regards it as a concomitant of the infective process and essentially an attempt to repair the ulcerative process. Gottlieb looks upon it as a part of the normal mechanism of eruption, though in pyorrhœa as a result of a morbid stimulus the epithelial proliferation may be excessive and aid in the formation of a pocket. Box studies the appearances from the standpoint of morbid histology, while Gottlieb is more concerned with the mechanism of the pathological processes. Though they differ in their interpretation of the significance of the changes, the fact that each has independently observed and described the condition is significant. It may be hoped that their researches will stimulate other workers to study the eruptive process, for on the confirmation of Gottlieb's heterodox views on eruption the validity of his conception of the pathology of pyorrhœa must depend.

"Ne quid nimis"

MEDICAL EDUCATION IN EGYPT

The political situation in Cairo is at present attracting general attention The outcome may well prove to be of great importance in regard to medical education in Egypt It will be within the knowledge of many of our readers that there was at the Kasr-el-Ainy Hospital a flourishing school of medicine chiefly under British guidance with many Egyptian medical men on the staff as physicians, surgeons, specialists, and teachers This school was recognised by the Conjoint Board in this country until about a year ago During the last two years many changes have occurred The English staff and teachers have for the most part been retired or replaced, though at the present time there is an English acting director or dean of the Faculty, who has been associated with the school for many years as professor of surgery and surgeon to the hospital The Minister of Education in the Ministry which has recently resigned has invited Sir Cooper Perry, who is just retiring from the post of principal officer of the University of London, to go out to Egypt in October to reorganise the medical school as a faculty of the new University of Cairo Sir Cooper Perry, by his long experience of university matters, notably as Vice-Chancellor and principal officer of the University of London, is well qualified for this work, and he has, moreover, the great advantage of previous experience of the Egyptian Medical School, as it was on his report that the Kasr-el-Ainy School was so successfully organised nearly 30 years ago We are also informed that it is proposed to appoint Englishmen to certain important professorial posts on the new Faculty of Medicine We welcome the news that the reorganisation of the School of Medicine is to be taken seriously in hand, and we feel sure that Sir Cooper Perry is the right man to do this in a statesmanlike manner with due regard to the special problems of Egyptian medical education Prof F. C Madden who is acting as dean of the Faculty of Medicine until Sir Cooper Perry's report is complete, has already made some changes tending to place the work in the school on a more satisfactory basis We have on more than one occasion pointed out in The Lancet the great opportunities which Cairo offers for medical education and research, and we have been glad to publish some of the original papers from the workers there both European and Egyptian We are convinced that under wise guidance and with genuine national support the Cairo Medical School can become the most important medical centre in the Near East The present developments give grounds for hoping that the Egyptian Government recognises these facts The experience of the last two years has demonstrated how rapidly a well-organised and effective institution can deteriorate when popular clamour sways the authorities and when ill-advised partisan interference is permitted We venture to hope that Sir Cooper Perry will evolve a means of establishing a genuine faculty of medicine and that the Cairo School will again become efficient even more rapidly then it has deteriorated

THE CHANGES IN THE BLOOD IN CONVULSIVE STATES

Interesting observations on the changes in the blood in convulsive states are recorded in the number of the *Bulletin of the Johns Hopkins Hospital* for June, 1926 O Wuth, using as his subjects epileptic patients, observed very definite changes in the blood following upon convulsions, these changes taking the form of a polymorphonucleosis and an increase in non-protein nitrogen, uric acid, and creatinine These changes were pronounced in all the cases observed, and in less careful hands might have led to the construction of an elaborate theory as to the causation of epilepsy or at least of epileptic convulsions Fortunately the author was not content to let the matter rest at this stage but controlled his results with observations on a series of cases of traumatic epilepsy, cerebral syphilis, and general paresis, in all of which violent convulsions were occurring In all cases exactly the same changes were found in the blood as in the cases of true epilepsy The author concludes that the changes found are the result of the violent muscular exertion during the convulsive seizures and have no relationship to the causation of the convulsions

In the same number of the *Bulletin*, Stander and Radlett describe the changes found in the blood of eclamptic patients after convulsive seizures These authors find the outstanding changes to be an increase in the non-protein nitrogen and uric acid as noted by Wuth in his epileptic cases, and also a decrease in the CO_2 combining power of the blood, a hyperglycæmia, and a great increase in the lactic acid The increase in the uric acid they are inclined to regard as a result of the liver damage which is so marked a feature of the eclamptic condition, in view of the fact that a similar change was found by Wuth in his cases of convulsions from various causes, it seems likely, however, that this increase is the result only of the convulsive movements, and is not specific to the eclamptic condition Three possibilities are suggested as to the cause of the striking increase of the blood lactic acid in eclampsia (1) an abnormally great amount of carbohydrate metabolised, (2) a disturbance or slowing down of the "lactic acid to glycogen" step in carbohydrate metabolism, and (3) lactic acid production from sources other than carbohydrate It was found that the administration of insulin caused a rapid reduction of the lactic acid to normal but left the uric acid level unaffected This might seem to point to the second suggestion as offering the correct solution Unfortunately no observations on this point were included in the work of Wuth In view, however, of the fact that lactic acid is excreted in considerable amount during exercise it would seem possible that the increase of the blood lactic acid during eclamptic convulsions may also be due to the violent activity of the musculature and in no way specific to the condition

THE TRIGEMINAL NERVE IN OPHTHALMOLOGY

In an article on the trigeminal nerve, which appears in the June issue of the *British Journal of Ophthalmology*, Mr Leslie Paton gives a useful résumé of our present knowledge In a sense the fifth nerve is involved in all ocular lesions, for its distribution and central connexions afford explanations of ocular pain, ocular headaches, and various ocular reflex phenomena There is, however, a more intimate association between lesions which involve the nerves of the eyeball and certain affections of the cornea Of this association the simplest example is the recurrent erosion of the cornea which occurs as a result of an abrasion causing injury to the superficial plexus of nerve fibrils Other examples are discussed by Mr Paton and include herpes of the cornea, herpes zoster ophthalmicus, and neuroparalytic keratitis The first—simple herpes—is associated with an ultra-microscopic filter-passing virus whose transmissibility has recently been demonstrated by W Gruter, and which is also found in connexion with labial and facial herpes Infection of the rabbit's cornea with this virus may lead to an infection of the central nervous system similar in its nature to encephalitis lethargica, and it has been shown that when this happens the infection travels to the bulbo-spinal root either along the axis cylinders of the fifth nerve or along the perineural lymph spaces In the eyes the most usual manifestation of herpes corneæ is a dendritic ulcer, but similar ulcers may be produced in the absence of herpes virus by the action of other toxins The slowness of healing and the tendency to recurrence which make dendritic ulcers so troublesome depend on the extent of the neural involvement Herpes simplex follows various infections of different kinds which produce a lowering of general tissue resistance. Herpes zoster ophthalmicus is a totally distinct disease and is strictly analogous to ordinary shingles. It follows the distribution of the affected nerve and arises independently of any preceding disease, though there is always a preceding neuralgia. Some or all of the branches of the first division of the fifth may be affected. In just over 50 per cent of the cases the globe is involved and in the majority of these it is the cornea which is attacked. As the naso-ciliary branch is distributed both to the globe and to the side and tip of the nose, the involvement of the latter is an important guide to prognosis. The most frequent primary manifestation in the cornea takes the form of small round-celled infiltrations in the substantia propria; vesicles, secondary infection, iritis, and even optic neuritis may occur later. The primary lesion always occurs in the Gasserian ganglion just as the primary lesion in ordinary herpes zoster occurs in the posterior root ganglion. Herpes zoster may occur in an epidemic form, and it has been shown that it then has a close relation to chicken-pox.

There remains to be discussed neuropathic keratitis. This is a condition in which marked degenerative changes are found in the cornea as the result of lesions affecting the fifth nerve, apparently in any part of its course. In Mr Paton's experience the lesion is common after operations on the Gasserian ganglion for the relief of trigeminal neuralgia—either extirpation or the injection of alcohol; but it may arise from lesions of the nerve either above or below the ganglion. The cause of the condition has not been satisfactorily determined. Some theories lay the main stress on the nervous factor in causation, either by means of a trophic influence or by means of vaso-motor fibres. Others attribute the corneal lesions to trauma due to diminished sensibility. Clinically there is good evidence of a combination of these causes being responsible. It is a remarkable fact that to prevent these lesions or cure them in their initial stage it is only necessary to unite the two lids by a temporary suture, and this seems to show that trauma is really the main factor. It is not necessary, however, that the whole cornea should be covered; a small lid adhesion as far as the outer side of the cornea appears to be sufficient. This is a very curious fact, and Mr. Paton does not offer any explanation of it. Trauma can hardly be the sole factor at work, for in rare cases the first manifestation of the herpes is not keratitis but iritis. Some observers have attributed the condition to dislocation of the vaso-motor mechanism, others to drying of the cornea owing to loss of sensibility; others again, to bacterial infection. Mr Paton considers all these theories unsatisfactory, and suggests that the problem requires further investigation. Useful information, he believes, might be gained by careful research, and to any such work his summary is certainly an excellent introduction.

STUDIES IN ARTIFICIALLY INDUCED MALARIA.

Malaria is to-day the treatment of choice for general paralysis of the insane. It is also being increasingly used for tabes dorsalis and for disseminated sclerosis. If it has blessed those receiving it, it has blessed also those giving it, for critical observation of this artificially induced disease has made important additions to our knowledge of malaria. Clayton Lane[1] gives a critical summary of this new knowledge of malaria gained from its therapeutic use.

Infection may be produced by (1) subcutaneous, intramuscular, or intravenous injection of blood containing malaria parasites, generally *Plasmodium vivax*, the infection being received as trophozoites; or (2) in the natural manner by the "bites" of mosquitoes, usually *Anopheles maculipennis*, which have been infected deliberately by feeding on malaria cases with gametocytes in the cutaneous blood, the infection being received as sporozoites. These methods may be designated "injected" and "natural," respectively. They are sufficiently distinct to necessitate caution in transferring to the one inductions made upon the other. In "injected" infections disinfestation is extraordinarily easy, 3 to 10 g quinine has brought about cure. After "natural" infections relapse much more frequently follows the same dosage of quinine. Clearly infections acquired as trophozoites react to quinine differently from those received as sporozoites. In spite of the much higher probability of malarial relapse the friends of the patient sometimes prefer the sporozoites—they do not like the idea of injection of insane and syphilitic or unknown blood; and this being so the doctor is safer from later charges if he give sporozoites and not trophozoites. The incubation period of "injected" cases has varied from 5 to 35 days, and has differed with the tissue site of infection. 4 to 8 days intravenous, 6 to 35 days subcutaneous, 10 to 16 days scarification with application of the blood. Two patients inoculated at the same time with the same quantity of the same blood may have quite different incubation periods, and it is wise to inform the patient's friends of this variability. Mühlens has insisted on daily examination of the blood to ascertain that a new strain of *P vivax* is pure. Deaths have occurred from unsuspected contamination with *P. falciparum*. Yorke and Macfie record that when deliberately using *P falciparum*, and making daily blood examinations by way of apparently adequate safeguard, deaths have occurred from fulminating cerebral malaria. Once a pure strain of *P. vivax* has been established it has been maintained for years, whether transmitted by "injection" or "naturally"; and has throughout retained the morphological characters of *P vivax*, irrespective of season. The "unicity" theory has broken down completely at the first experimental test. Many observers have proved that gametocytes may eventually form even after many passages in which they have not been observed in injected cases. There is no justification for the conclusion held by some that "injected" cases are no risk to anyone. Again, the same strain of *P vivax*, passed on by injection, may produce different reactions in different hosts. It may seem to require refreshing, or become very virulent for a time. The mortality emphasises the need not only for daily observation of the blood, but for critical clinical regard for the patient as well. It has been pointed out above that the results of quinine treatment of "injected" cases are better than those of mosquito-infected cases; yet even these last are an enormous improvement on those obtained during the Great War, in the same hands, in established cases; and they indicate the vital importance of immediate and adequate treatment of all early malarial infections. As a prophylactic Yorke and Macfie noted that 10 gr. of quinine taken daily for five days before and seven days after infective mosquito bites failed to prevent infection. This could be ensured only by continuing this quantity of quinine for ten days after the infecting bites. Against the sporozoites, then, quinine is ineffective and of little or no prophylactic worth unless taken in curative doses, a conclusion which confirms Hanschell's African observations. Quinine does not act directly on the plasmodia, for blood containing parasites and quin hydrochlor. 1 in 10,000, for 12 hours, or 1 in 5000 for five hours, may yet infect by injection. Quinine given to a donor does not render his blood malarially harmless to the recipient. Malarial parasites are not destroyed when incubated at body temperature with blood containing quinine in far greater strength than can be found in vivo. Yorke and Macfie conclude that quinine destroys, probably indirectly, large numbers, but not all, of the parasites, thus setting free a quantity of soluble antigen to provoke formation of immune body, which destroys yet more parasites. A. Pijper and B Russsell report from South Africa that after injection of benign tertian malaria the red blood corpuscles increase by 10 to 30 per cent. before fever appears, and that fever can be cut out by neosalvarsan injections It may be added that benign tertian infections by "injection" or by mosquito bite do not at first show the tertian intermittent fever seen in established cases The fever at first is irregularly remittent, even typhoid-like, and when, later, the intermittent form appears, it is quotidian This temperature course was demonstrated by the historic case infected by Manson in 1900, in London, by mosquitoes brought from Rome home, but though the case was always remembered its temperature chart was forgotten

[1] Tropical Diseases Bulletin, May, 1926, vol. xxiii., No 5.

These are only a few of the many important observations to which the study of malaria as a therapeutic agent has led It will be some time before they can be woven together into a comprehensive whole, but meanwhile much light has been thrown on various aspects of the problem From the epidemiological standpoint the recent communication of Colonel S P. James to the Royal Society of Tropical Medicine and Hygiene, which was reported in The Lancet of June 26th may be of great practical importance The results of his recent researches are set out at greater length in a report[1] published by the League of Nations He has found a close correlation between his field observations of *A maculipennis* and European malaria and the facts disclosed by his laboratory breeding and malaria infecting of this mosquito for therapeutic use in G P I The one showed these mosquitoes haunting and breeding in and about the houses of malaria subjects—a house infection with malaria, the other that *A maculipennis* needs a definitely sheltered existence to acquire and maintain infestation with malaria This presages a shift of anti-malarial effort from the swamp to the household, and will need an organisation of tactful health visitors in tropical lands even more specialised than those who carry out such work at home, if it is to be successful

TEACHING AND LEARNING

The foreword to the Report of the Scientific Work of the Surgical Staff of the Women's Hospital in the State of New York for the year 1923–24,[2] states that the surgical staff are expected to utilise every available opportunity in the hospital by engaging in clinical research and making studies from their records, and the present volume, which consists of 27 monographs by the staff and seven theses by the senior students of Cornell University Medical College, is one of which any hospital might be proud Every article in the volume is the result of observation or research The cases are analysed in elaborate tables and the operative methods employed are excellently illustrated; both tables and illustrations speak of an organisation and of financial resources entirely inaccessible to the English surgeon But to our mind the remarkable portion of the volume is the latter half, containing theses contributed by undergraduate fourth-year students as part of their work in the department of gynæcology for their degree at Cornell Students taking the elective course in gynæcology are given problems as part of their work Two students are assigned to a problem and they work up the data together, but each submits a separate thesis There are here published seven of these theses They reach a really high order of merit showing close observation and thoughtful analysis of the clinical facts that have been recorded To have carried out one such piece of work is a thing of which any medical student might well be proud, and its effect upon the mind of the student can scarcely be exaggerated These theses are on such practical points as post-operative leucocytosis, the end-results of carcinoma of the ovary, the incidence of carcinoma of the cervix following supravaginal hysterectomy the effect of ether anæsthesia on the isoagglutinins of the blood, the results of blood transfusion, the treatment of incomplete abortion and pyelitis as a post-operative complication

Of course no student could produce such theses without a great deal of assistance, but a study of each article shows at once that it has been so arranged that the actual work could be carried out by the students themselves Here we have a method of teaching to which the reformers of medical education in this country might well have their attention directed The scheduled life to which for years our senior students are condemned in an overcrowded curriculum compels them to keep closely to the beaten track if they are to satisfy the examiners Facts must be learnt, but ephemeral theories need not be crammed, a plan which would allow the student, if only for a short space, to breathe the air of research, to observe facts for himself without anticipation of an examination to be faced, calls for serious attention And there is the chance that the properly guided student might produce something useful for the world while working with infinite value to his own mental development Our education authorities have laid much emphasis in the past on the verb "to teach" This volume should serve to remind us of the importance of the verb "to learn"

ETHYLENE ANÆSTHESIA AND CARBON MONOXIDE POISONING

Three cases, two of which were fatal, of collapse after inhalation of ethylene are reported in the *Journal of the American Medical Association* (June 5th), and in two of the patients carbon monoxide was proved to be present in the blood to the extent of 50 and 60 per cent saturation. This report appears to be an important contribution to the literature of ethylene, and marks the desirability of a rigid test of the contents before cylinders of ethylene are put into use The manufacture of this agent for anæsthetic purposes has been on the increase in this country, where, until recently, the only ethylene available for anæsthetists came across the Atlantic, and we do not doubt that the lesson of these cases reported from Pittsburgh will be given due attention In all these three instances, in one of which the period of anæsthesia was 50 minutes, the signs of collapse did not appear till the operation was almost completed Forced inhalations of oxygen with 10 per cent carbon dioxide were the chief remedial measures employed Besides the cylinders used for the patients referred to above, two other fresh cylinders of ethylene were examined for carbon monoxide with positive results. It is satisfactory to note that the problem is being further investigated in collaboration with the United States Bureau of Mines at Pittsburgh

SURGICAL TREATMENT OF BRONCHIECTASIS

Established bronchiectasis is so intractable that recourse to heroic measures may well be justifiable Modern thoracic surgery provides several alternatives The success of treatment largely depends on early diagnosis and as Brauer[1] has pointed out in discussing the advantages of artificial collapse of the lung, the condition presents many different clinical and anatomical pictures It starts, perhaps, with a simple bronchitis and broncho-pneumonia, and goes on with remissions for many years before developing the classical symptoms of the advanced disease Initial stages are frequently overlooked and the diagnosis may not be made until the case requires energetic treatment A persistent localised catarrh should always be suspect When bronchiectasis is diagnosed in the earlier stages it is difficult to decide how soon active intervention should be attempted Brauer considers it indicated if there is copious offensive expectoration, extension of the trouble, a predisposition to hæmorrhages or recurrent broncho-pneumonia, or an irritating and painful cough If intervention is decided on there are three possible procedures—collapse of the lung, pneumotomy, or resection of a lobe or lung. Brauer favours the first of these on the ground that it is the least dangerous; but it must be done in time if it is to be efficacious. The object of all treatment must be to prevent stagnation of the secretions, which occurs in the saccular dilatations along the bronchi; the bronchi between the saccules are relatively, if not actually, stenosed. The lung tissue adjacent to the bronchitis is involved by an interstitial peribronchitis, and the resulting fibrosis and dilated bronchi do not yield readily to collapse, though improvement does occur from the immobilisation associated with it. When the pathological changes are advanced, therefore, collapse by thoracoplasty is insufficient unless such collapse is very nearly complete. Artificial pneumothorax is an alternative, but it is generally impossible to secure in adults owing to the formation of adhesions. If practicable, it may be effective; but it has to be maintained. Thoracoplasty should be extensive and should be done by the subscapular-paravertebral technique; it has the advantage of maintaining a permanent collapse. Phrenicotomy is useful in slight cases, but as a general rule it has to be combined with other methods.

PUBLIC HEALTH AND MEDICAL PROFESSION IN OVERSEA LEGISLATION

THE latest volume of the *Journal of Comparative Legislation* contains summaries of the laws passed during 1924 in the British Isles and the Dominions overseas. From this bird's-eye view it is possible to see what progress has been made lately by British legislatures in matters affecting public health and the medical profession. Southern Rhodesia took advantage of its new status as a colony to pass a comprehensive Public Health Act largely based upon the law of the Union of South Africa. The Act declares the functions of the Public Health Department to be to guard against the introduction of disease into the colony, to prevent, limit, and suppress infectious and contagious diseases, to advise and assist local authorities, to promote and carry on research, to prepare and publish reports, statistics, and other information, and generally to promote public health. The Minister obtains wide powers of making regulations and is given the assistance of an advisory board. Quebec and Saskatchewan have also passed public health measures, the central authority in the latter province being empowered to prohibit, for such period as is deemed advisable, the holding of public meetings or gatherings in case of an epidemic, or threatened epidemic, and upon request of the local board of health or medical officer. Manitoba has passed an amending Act which repeals the requirement that small-pox cases be removed to isolation hospitals; other sections deal with fumigation, the entering of sick-rooms with the permission of the health officer, the duty of occupants of “placarded houses,” permits to go about one's usual vocation, and the cleaning of rooms and clothing after cases of communicable disease have occurred. Alberta has re-christened its Insanity Act, which in future will be called the Mental Diseases Act, and has changed its “asylums” into “hospitals.” The superintendent is authorised (*a*) to admit to hospital and detain for examination and treatment such person as he may deem proper; (*b*) to order a patient's removal from one hospital to another; (*c*) to discharge a patient who no longer needs treatment; and (*d*) to release patients upon probation if satisfied that the patient will during the necessary period be properly looked after by relatives and friends. Any resident in Alberta who needs, or is believed to need, treatment for mental diseases may be admitted to hospital (*a*) by voluntary submission to treatment, (*b*) by medical certificate, or (*c*) by warrant of the Attorney-General. Anyone who believes himself to need treatment may voluntarily apply for admission and may be received and detained. There is machinery by which two legally qualified medical practitioners may certify that they have specially examined a named patient and that he should be confined in a hospital; on these certificates being submitted to and approved by, the superintendent, the patient may be removed to hospital without any further or other authority. Drug addicts are to be deemed persons in need of treatment such as is provided in a hospital, and the provisions of the Act relating to insane persons are made applicable to addicts. Bermuda has authorised the appointment of a director of the medical and health department at a salary of £1000 plus travelling expenses from and to the United Kingdom.

Amongst enactments relating to medical practitioners a New Zealand Act contains important provisions. The original Act of 1914 gave the holders of certain “foreign” diplomas an absolute right to registration, subject to certain conditions as to reciprocity. In future the registering authority may require the holder of a “foreign” diploma to pass an examination in medicine and surgery prescribed by the University of New Zealand; this condition may apply even if the applicant is registered in the United Kingdom, provided that his registration in the United Kingdom is by virtue of such “foreign” diploma. The new Act also provides for removing names from the register of New Zealand where persons have been registered there on the strength of outside qualifications, and where they have been removed from the registers of their original countries on grounds of misconduct. There is a right of appeal to the Supreme Court against such removal. The Medical Council of New Zealand, which is the registering authority, is given new disciplinary powers in cases of “grave impropriety” or “infamous conduct in a professional respect.” If the conduct is not regarded as so grave as to render removal from the register necessary in the public interest, the Council may impose fines or suspend from practice, but the suspending order is not to exceed a period of 12 months nor can it be made without the consent of the Attorney-General. There is a right of appeal to the Supreme Court against all orders imposing penalties. Lastly, a medical practitioner who has been temporarily detained in a mental hospital must not resume practice without first obtaining a licence from the Medical Council. New Zealand has also passed a Masseurs' Registration Amendment Act containing an elaborate definition of “massage,” definitely declaring that “chiropractors” are not entitled to be registered as masseurs. New South Wales has established a Board of Veterinary Surgeons; practice as a veterinary surgeon is to be restricted to persons registered under the law, and registration is to be confined to persons who satisfy the Board of their qualifications, good fame, and character. Under another Act there is to be a Nurses' Registration Board of New South Wales with powers to arrange and hold examinations, to register qualified nurses, issue certificates of registration, and remove or suspend from the register any nurse guilty of misconduct. The general provisions are not unlike the English, Scottish, and Irish enactments of 1919. Existing nurses, if they satisfy the Board as to their qualifications, may be registered. After 12 months from the commencement of the Act no one may assume the title of nurse unless registered, nor may any registered nurse act, except in cases of urgency, in any capacity in which she is not registered.

Other enactments in these summaries of overseas law-making (which the Society of Comparative Legislation annually publishes) deal with matters which have their bearing upon public health and their interest for the medical profession. The State of Victoria, for instance has dealt with the diseases of animals and with traffic in carcasses, the Irish Free State with agricultural produce—eggs and butter, and Northern Ireland with the marketing of eggs; while New South Wales has passed a Plant Diseases Act to protect plants and fruit from diseases and insect pests, with wide powers of declaring quarantine areas, inspecting infested districts, and destroying infected plants These are but a fraction of the general wealth of information on all topics which a study of comparative legislation reveals That study is particularly interesting when it shows, as in the case of the New Zealand legislation concerning medical practitioners discussed above, how far the laws of the home country, often attacked by critics, have been adopted and extended in progressive democracies elsewhere

---

THE TRANSMISSION OF KALA-AZAR

The Indian Research Fund Association has published a memoir [1] which embodies the report of the Kala-azar Commission in India and contains numerous other papers, including those of the Kala-azar Ancillary Inquiry The work done and the results achieved are so important that it is necessary to say something of the Commission's constitution It was formed in 1924 and has worked in conjunction with the ancillary inquiry, which was staffed by the Calcutta School of Tropical Medicine, the object of the two bodies has been to make a general survey of kala-azar in India, more especially paying attention to the manner in which the disease is transmitted The Commission consisted of Lieut-Col S R Christophers (director), Major H E Shortt, and Mr P J Barraud, while the members of the ancillary inquiry were Major R Knowles, Dr L E Napier and assistant-surgeon R O A Smith The conclusions at which the Commission arrived are now widely known, and the implication of the sandfly (*Phlebotomus argentipes*) as the transmitting agent are manifestly of far-reaching importance It is obvious that the work has been done with great deliberation and that the conclusions are mature The bed bug was given full consideration as a possible vector but when carefully weighed in the scales of evidence it was found wanting, and so has been exonerated In the same way, chiefly on the basis of work done by Mackie in Assam in 1915, the common louse has been excluded The papers are prefaced by an excellent introduction by Colonel Christophers, in which he surveys previous investigation into the transmission of the disease, and whets the reader's appetite for the more detailed account in the report The description of the geographical distribution of kala-azar is as interesting as it is instructive One of the most striking finds of the ancillary inquiry is the fact that no less than 25 per cent of sandflies fed on kala-azar patients became infected with leishmania flagellates in spite of the fact that in the patient's peripheral blood stream the parasites are always apparently very scanty indeed The infection manifests itself in the production of masses of leptomonas forms in the pharynx of the sandfly The parasite of kala-azar should therefore be known as *Herpetomonas donovani* The Commission found it difficult to recognise this sandfly as an efficient vector, for the reason that infected flies seem in the normal course to die after oviposition, within five days of their being infected none the less, so strong is the evidence of implication that it is considered that "for the present the sandfly must be held to be the probable transmitter" The written matter of the memoir, as we have indicated, is of great interest, and the numerous illustrations and diagrams which are scattered throughout the volume make it for all time a mine of information upon the anatomy and biology of phlebotomus in India The work done by the inquiry Commission will have well repaid the Indian Government for its energy and enterprise, and it is indeed gratifying to announce that certain conclusions, the promise of which is carefully guarded, have been reached The devoted band of workers concerned are to be cordially congratulated on the consummation of their labours

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CLXXXI

TREATMENT OF PERSISTENT HICCUP

Hiccup is due to a spasmodic contraction of the diaphragm, causing an abrupt inspiration which is cut short by a sudden closure of the glottis

Causation

The causes of persistent hiccup are manifold. Nothing is more exhausting to the patient, or more capable of making life a misery, or dying a torment than persistent hiccuping, after operation no symptom is more difficult to allay, or more painful A careful consideration of the source of the irritation will go far to promote successful treatment Very commonly the centre of irritation causing the spasm is below the diaphragm

Subdiaphragmatic Conditions—Distension or overloading of the stomach is a common cause of troublesome hiccups The effect of alcohol in its production is proverbial Hiccup may occur in association with abscess of the liver irritating the under surface of the diaphragm, similarly new growth in this situation may also cause the symptom, which is also met with in cirrhosis of the liver Peritonitis of the upper part of the peritoneal cavity, including subdiaphragmatic abscess, sometimes causes the spasm

Pleural Conditions—Irritation of the pleural surface of the diaphragm, such as is set up by diaphragmatic pleurisy, or an empyema, is often a cause Occasionally hiccup is produced by infiltration of a new growth in this area, arising perhaps at the lower end of the œsophagus or by metastasis from some other place.

Phrenic Irritation—Direct irritation of the phrenic nerve as a cause is rare, but irritation may be set up indirectly by new growths of the mediastinum or enlarged glands at the root of the lung Such lesions much more commonly cause paralysis of the phrenic nerve

Central Causes—Very often hiccup is a most troublesome symptom in uræmia owing to poisoning of the medullary centres It may be met with in typhoid fever in this way Cerebral irritation set up by a hæmorrhage or a tumour may cause persistent hiccuping A very intractable and persistent form was often met with at the time of the influenza epidemic and gained the name of "hiccuping 'flue'" In all probability the cases were mild forms of encephalitis lethargica, and the symptom was not uncommon in well-marked cases of the disease

Finally, hiccup may be purely a functional phenomenon associated with an hysterical condition

Simple Measures

As regards the milder cases one can hardly do better than quote the famous passage in Plato's Symposium It was the turn of Aristophanes to make a speech, "but either he had eaten too much or from some other cause he had the hiccup, and was obliged to change turns with Eryximachus the physician" Said Eryximachus, "Let me recommend you to hold your breath, and if after you have done so for some time the hiccup is no better, then gargle with a little water, and if it still continues, tickle your nose with something and sneeze, and if you sneeze once or twice, even the most violent hiccup is sure to go" The treatment was successful, Aristophanes said a little later, "the hiccup is gone, not, however, till I applied the sneezing and I wonder whether the harmony of the body has a love for such noises and ticklings, for I no sooner applied the sneezing than I was cured"

To such simple measures in the milder cases may be added the trick of drinking from the wrong side of a glass, which naturally causes stretching and drawing in of the epigastrium The arms may be kept held above the head for a few minutes, or the knees drawn up and the thighs flexed on the abdomen, so as to cause pressure on the epigastrium, this posture being maintained for five or ten minutes Firm pressure with the hand on the epigastrium for a few minutes may be effective No doubt an important factor in curing the attack is getting the attention of the individual fixed on something other than the expected hiccup

In the more persistent cases such simple remedies fail and more potent methods must be tried

Counter-irritation

Pressure on the eyeballs or on the supraorbital nerves may be effective, especially in an hysterical case A blister may be raised in the sensory area of the third and fourth cervical nerves at the root of the neck just above the clavicle Steady traction on the tongue for one or two minutes may be successful A mustard plaster may be applied to the epigastrium for 10 or 15 minutes, or mild faradism used over this area For a person who can stand it, a cold shower bath may cut short an attack of hiccuping Direct pressure may be tried over the phrenic nerve 2 inches above the clavicle at the outer border of the sternomastoid or light massage given at this spot

Where basal pleurisy is present a tight band of strapping round the lower ribs applied in expiration may be very effective

Gastric Cases

If the cause of the trouble is in the stomach carminatives are useful A drachm of spirit of chloroform may be given and repeated every four hours, or a teaspoonful of sal volatile in a little hot water Five to ten minims of the tincture of capsicum in a little water has proved efficacious Five minims of the spirit of camphor may be given in milk or on a lump of sugar Five minims of turpentine in a capsule is worth trying If there is marked dilatation of the stomach the attack may be relieved by passing a stomach-tube and washing out the stomach with a 2 per cent solution of sodium bicarbonate This is, however, of no use in cases in which the cause is other than gastric Patients whose hiccups are milder, are associated with indigestion, and occur after meals should be cautioned against eating too much or too quickly, for them an acid and bitter mixture is useful, or alkalis if they suffer from acidity

Central Causes

In toxæmic conditions such as uræmia, treatment of the cause will naturally lessen the tendency to hiccup, but it may not be possible to combat the cause rapidly, and the symptom may persist obstinately even in those cases in which surgical treatment of the underlying condition is carried out The symptom must be treated empirically, there are a variety of drugs which may be tried In a persistent case it is advisable to withhold all solid food

The following remedies have proved useful —

1 Atropine hypodermically, gr 1/100, to be repeated in four hours if required, or tincture of belladonna ♏ x every four hours Benzyl benzoate may be given in a 20 per cent alcoholic solution, 20 minims in milk, or as an emulsion every two hours

2 Sedatives may be tried These include hyoscine (gr 1/100), chloral, tincture of cannabis indica, the bromides, antipyrine, a large dose of sodium bromide may be administered per rectum Hoffmann's anodyne may be given, a drachm in iced water A hypodermic injection of cocaine may be tried (gr 1/30–1/25) Lastly, and by no means least, morphia is most likely to be successful in a severe case and may well be combined with atropine Sometimes a few whiffs of chloroform will check the spasm, especially in a functional case

3 In an obstinate case of obscure origin an emetic may bring relief, a hypodermic injection of apomorphine (gr 1/20–1/10) should be given

4 A capsule of amyl nitrite may be broken in a piece of wool and sniffed A tablet of nitroglycerine (gr 1/100) may be given every four hours, or the liquor trinitrini used in repeated doses, starting with half a minim and increasing the dose by this amount every three hours, till two minims at a time are given.

5 It may be necessary as a last resort to consider the injection of novocaine into the phrenic nerve at the root of the neck Both nerves must not be treated on the same day

Such drugs as those named above may prove effective, if one fails another must be tried The more simple methods will suffice in the milder cases, especially where there is a functional element Hypnotism even has been known to have success But where hiccup plagues the last stages of an incurable condition, morphia alone, in all probability, will bring relief and the euthanasia it secures should not be withheld

Junior Physician, King's College Hospital

Special Articles.

ROYAL SANITARY INSTITUTE
JUBILEE CONGRESS

(*Concluded from p 92*)

Sir George Newman, in his presidential address on July 6th to the Section of Sanitary Science and Preventive Medicine, submitted that factors other than sanitary science—good roads, political power, economic development, social customs and habits—have played a large part in bringing about the present condition of the public health After referring to the work of non-medical men who had advanced medicine, he went on to discuss propaganda, in which, he considered, the newspapers were playing an invaluable part

Dr W A Daley (M O H, Hull) and Dr A T Nankivell (M O H, Plymouth) read papers on propaganda in public health, and Dr G Clark Trotter (M O H, Islington) detailed methods suitable for small as well as large authorities Sir Thomas Horder advocated cremation, Dr John Poynton and Dr. Carey Coombs read papers on acute rheumatism, and Dr T Izod Bennett discussed the intestine in relation to the occurrence of chronic rheumatism

Port Sanitation

At the conference of port sanitary authorities Sir George Buchanan dealt with the International Sanitary Convention to be presented for ratification to the 53 Governments represented at the recent Paris meeting In the new Convention the requirements for clearing rats out of ships had been modified, inspecting officers could be empowered, if satisfied, to exempt ships from being so treated at the end of each six months Ports were not to be formally declared infected if a certain number of cases of dangerous infectious disease had occurred; but, by way of compensation, efforts were to be made to increase means whereby countries might obtain intelligence regarding the prevalence of infectious disease in all parts of the world

Dr A S M Macgregor (M O H, Glasgow) asked that port medical officers of health, when forwarding the names and addresses of contacts to the medical officers of health at the contacts' destination, should be required to state the degree of contact between the said passengers and the case of infection

School Hygiene

Lord Eustace Percy (President of the Board of Education), who presided over the Section of School Hygiene, said that the movement of the population from the centre to the outskirts of large towns made it possible to build the ordinary schools on open air lines The recent development of orthopædic schemes should eventually reduce the number of schools for cripples, and he expected much from the extension of physical training and of outdoor games for school-children It was the ideal of some that the child should be admitted as early as possible in its life to some form of school, but he thought that parents should endeavour to become independent persons, who should regard themselves as adequately fitted by training and knowledge to discharge their duties

Opening a discussion on the teaching of physiology in schools, Prof Winifred Cullis (Royal Free Hospital) said that medical students starting their work had a passion for disease, whereas they ought to have a passion for health The ideal was that general biology should be taught in the public elementary schools, emphasis being laid on the physiological or functional side The public, however, might consider that there was not time for exhaustive teaching of biology, and so stress should be placed on physiology The teaching of physiology could be educational as well as instructive Hygiene as taught in schools at present was not sufficiently based on physiological principles The text-books were unattractive and dwelt too much on uninteresting structure, such as connective tissues A suitable work for children must include information about reproduction

Dr Leonard Hill agreed that attention was concentrated too much on structure, even in the medical curriculum an excessive amount of anatomy had to be learnt He wanted school-children to breathe air with 5 per cent of carbon dioxide, so that they might see the results for themselves The athletes of a school should compare the results of running races with and without the help of oxygen

Councillor Julyan (Poole) thought the actual practice of school hygiene deplorable, children were to be given these excellent lessons in dark, ill-ventilated schools

Dr Dunstan Brewer (M O H, Swindon) said that future school-teachers, during their training, ought to learn the meaning of biological science and the possibility of its application to hygiene

Colds and Catarrh in Schools

Dr Clive Riviere said that colds and even influenza, which might have very serious consequences, were often considered trivial complaints by the public, people had great difficulty in realising that they themselves were centres of infection The avoidance of infection was impossible, all that could be done was to keep fit, employ radiant heat for warming, keep the air in rooms moving and warm the floor. Parties for school-children should be held not at Christmas but in the summer, and, as far as possible, in the open air The removal of tonsils and adenoids and the prevention of mouth-breathing might get rid of a few carriers After an atttack some children acquired greater immunity; in others it was lessened Prophylactic vaccine might give protection in some cases

Dr. A I Simey (Rugby School) said that preparatory and girls' boarding schools were less troubled than boys' boarding schools, in the former group there was more supervision, in some of them the temperature was taken daily for the first few weeks of term, and any suspected child isolated Infection was not endemic in schools, and a term of epidemic prevalence was invariably followed by one of comparative freedom Season and weather had very little to do with it

Dr L R Lempriere (Haileybury College) had ascertained that 25 per cent of the admissions to his school sanatorium were caused by catarrhal conditions Children should be taught to blow the nose properly, and the handkerchief should be held well away from the nostrils The effects of vaccines were sufficiently encouraging to merit further trial

Dr E B Morley (Mill Hill School) pointed out that the vaccines used were made from organisms which only produced secondary effects and that there was a great difference in their ingredients

A paper on open-air schools was read by Dr M D Horst (M O H, Leiden, Holland)

Hygiene in Industry

Addressing the Section of Hygiene in Industry Mr J R Clynes, M P, said that the conduct of educational and recreational activities should be left to the workers themselves Hygienic improvement in factories and workshops had done much, but wholly mistaken ideas as to motives had impeded the movement The workers suspected charity or thought that the work was being done purely in the interest of the employers, and those keen on trades-union interests thought that the more humane standards introduced would weaken self-defence as expressed in trades-union methods

Dr Thomas Watts, M P, expressed disappointment at the attitude of workmen to welfare work Only a few months ago, when visiting a cotton-mill, he had found that the workpeople would not avail themselves of the excellent cheap dinner provided at the canteen

Councillor Price (Hemsworth), in welcoming the Miners Welfare Act, mentioned the difficulty of getting land for purposes of recreation More safety appliances were wanted in mining, in 1924, out of 3000 men and boys employed in his mine no less than 1141 were injured in the pit and had to be treated at the colliery hospital

Dr H P Newsholme (M O H, Croydon) said that monotonous occupations diminished the alertness of the workpeople, their thoughts strayed while working, and a sense of grievance might creep in He was not in favour of too much specialisation of the workman's task

Prof E L Collis (Wales) opened a discussion on

The Future of the Factory Medical Service

There was not, he said, at present a full factory medical service The appointment of certifying factory surgeons, which began in 1844, had not proved adequate for the work to be done Prof Collis mentioned a large coal and iron works in the United States where 383 whole-time officials cared for 23 000 employees, he thought that the system of appointed doctors would prove the more satisfactory alternative for this country He did not think the local authority—by means, for instance, of an extended school medical service—could very well do the work for many workpeople lived outside their geographical area and could not be looked after during convalescence Again, the rates should not be spent to benefit only one section of the community But, recognising that the local authority desired to see that people employed in their areas were healthy, he thought that they might with advantage supervise any work done on behalf of the workpeople

Lieut -Colonel F E Fremantle. M P, maintained that the present system of carrying on factory medical work was not in accordance with the ideals of the Ministry of Health Act The Ministry of Health—one of the largest of all the ministries—could not take on more work and improvement in the service most be hoped for under the Home Office He thought that the system of appointed doctors could not be universal, as a large number of employers could not afford to appoint doctors Those appointed must work under supervision, and it was the function of governments to fill up the gaps The minor local authorities might not do this properly, and it should be done by the major local authorities He saw no force in Prof Collis's geographical considerations or his contention that the rates should not be spent on only one part of the community The milk industry had been benefited by money paid out of the rates, and public control must not be ruled out because it benefited only one part of the community The rights of those of the certifying factory surgeons who had proved their worth should be safeguarded, the Home Office medical staff should be increased and they should be independent of lay control, just as were the medical staff of the Ministry of Health with their right of direct access to the Secretary of State

Prof F E Wynne (M O H, Sheffield) agreed almost entirely with Prof Collis The desire for a real coordination of public health work at the centre and locally which had given birth to the Ministry had not been realised He objected to the work of looking after workshops being taken from sanitary inspectors The staff of the medical officer of health should control the hygienic conditions of factories as well, the present distinction as to which was a workshop or a factory was artificial and ludicrous

Dr Vernon Davies considered that the system of the appointed doctor would be unsatisfactory, he would be too dependent on the employer He agreed that the sanitation of factories was a duty of the local sanitary authority

Colonel P S Lelean (Edinburgh) said that applied physiology could provide the 3 (or possibly 5) per cent increase in output which would be such an enormous gain to industrial efficiency The Usher Institute of Public Health in the University of Edinburgh wished employers to send their problems to the Institute, but it had found difficulty in getting into touch with employers

Sir Thomas Legge (Home Office) said that Prof Collis, influenced by the success of the Silicosis Fund, had declared in favour of the appointed doctor but his arguments had been completely answered by Dr Vernon Davies Certainly, however, the appointed doctor under the last Factory Bill had to satisfy the workmen Ninety-five per cent of the medical services rendered to workmen were carried out under the National Health Insurance authority, and the work of the certifying factory surgeon should be linked up with that done under the Insurance Acts

Health Administration and Poor-law Reform

In the Section of Medical Officers of Health the President, Dr G F Buchan (M O H, Willesden), discussed the optional size of the unit of health administration A system of block grants, he thought, would stimulate the expansion of health services

Dr T Eustace Hill (M O H, Durham C C) referred to the lack of cooperation of boards of guardians with local health authorities He was in favour of the transfer of the personal services from county councils to the whole-time rural medical officers of health who at present had not sufficient work to keep them interested

Dr H B Brackenbury (British Medical Association) pointed out that health administration was not yet coordinated centrally or locally Local authorities could easily cope with the extra work which it was proposed to transfer to them He agreed that possibly the National Health Insurance officials did not like the proposed transfer, they did nothing to counteract the impression among those insured persons who attended meetings that such a transfer would mean pauperisation of the insured person The present financial basis of National Health Insurance administration would not necessarily be altered The mixed functions of the Poor-law guardians—health, education, and assistance—must be separated, and not transferred en bloc to a new committee of the local authority Topography and historical associations necessarily had to be considered in fixing the boundaries of local administration units, and the county and the minor authority must not both have jurisdiction on health matters in the same unit

Mr H L Eason (Guy's Hospital) said that in any municipal hospital the service provided ought to be of the same standard as that of voluntary hospitals

Dr Spencer Mort (Edmonton) described the North Middlesex Hospital and detailed a scheme for a public hospital service

Dr A E Cope (Poor-law Medical Officers' Association) welcomed the proposed transfer The Poor-law medical officer, he said, was at present ignored by boards of guardians and had no opportunity of making his voice and views heard at their councils The parish doctor was treated with contempt by everyone If they were to come into closer contact with the medical officers of health, he felt sure that their views would receive consideration

Dr J Fenton (M O H, Kensington) pointed out that in metropolitan boroughs no less than five health bodies had functions The consequence was overlapping and duplication of the work and the best results would only be got when an individual's health was dealt with by one local authority throughout his life The borough medical officer could not envisage the health of his area as a whole nor could the county medical officer The work now done by the London Insurance Committee and the non-residential institutional work now done by the Poor-law authorities (including vaccination) should be transferred to metropolitan borough councils The London County Council, under the scheme put forward by the Minister of Health, was to control no less than 70,000 beds, the size of which task could be judged when it was remembered that there were only 13,000 beds in all the voluntary hospitals of London The London County Council would remain the supervising and coordinating authority for health services generally Central executive administration over the metropolis must of necessity be bureaucratic, the London County Council should act as a provincial board of health for London, thus relieving the Minister of Health of much of the detailed work now falling upon him

Mr R H P Orde (British Red Cross) said that the only real fault of the voluntary hospitals was that there were too few of them The voluntary hospital had tacitly confessed its inability to cope with the situation and the State must fill the gaps In the newer parts of the United States of America there were only municipal hospitals, in others the municipal hospital ranked, if anything, above the voluntary hospital

Demonstrations and Visits

Other subjects considered by Sections included personal and domestic hygiene and the housing of the poor An evening address was given by Prof C E A Winslow (Yale) on the appraisement of health administration

A demonstration in the hygiene laboratories of the Royal Army Medical College was one of the most interesting features of the Congress An admirable demonstration was given of the Douglas Haldane method of indirect calorimetry by means of which the new British Army equipment was evolved The pack is to be carried high on the back By photographing the movements of a light on the end of a shovel, handled by an expert digger, the most profitable motions in digging have been worked out, and these are now taught to recruits The new army emergency ration, which weighs 20 oz instead of 30, was exhibited It consists of biscuits, pemmican, chocolate, and blocks of tea, which, in the absence of water, can be eaten

Visits were paid to the Port of London and elsewhere, and a number of receptions were held

The Congress was attended by 1850 members 1200 of whom were sent by local authorities

DINNER OF THE CONGRESS

The dinner was held on July 8th at the Hotel Cecil The Duke of Northumberland, President of the Institute, presided, and more than 500 people were present

After the toasts of "The King," the Patron of the Institute, "The Queen and the Royal Family" had been honoured, Dr Charles Porter proposed "The Navy, the Army, and the Air Force" Surgeon-Commander J L Priston said that when some new sanitary measure for the Navy was in question, the success that measure had achieved in the hands of the Royal Sanitary Institute always convinced those who opposed Colonel H P W Barrow said that the Army and the Institute were closely connected in their work. The Parkes Museum was founded in honour of an Army surgeon, and the Institute, like the Army, had helped to train sanitarians Replying for the House of Lords, Lord Burnham regretted that so little use was made of the administrative ability of that House in examining questions of health and local government Lieut -Colonel F E Fremantle for the House of Commons, said that Members were all united in their support of hygiene, but members of the Institute should assist their representatives in the House by their expert advice Sir John Gilmour, Secretary for Scotland, proposing the health of "The Royal Sanitary Institute," said that the Institute, in its 50 years, had done much for sanitation in England, was now active in the Dominions, and latterly had made a great advance by enlisting women and teaching them to help Prof A Bostock Hill, Chairman of the Council of the Institute, in reply, regretted the enforced absence of the Minister of Health, and thanked Mrs Chamberlain for her presence He said that though we had not yet reached the city of Hygeia, as pictured by Prof Kenwood in a recent number of the *Journal* of the Institute, the roads thither had been made more easy for travellers by the Institute's 50 years of work In the old days the poet had said —

> "The cottage homes of England, how fearfully they smell,
> There's fever in the ashpit, there's sewage in the well"

but, to-day —

> "The cottage homes of England, in them we now find health,
> And bright and happy children, who are the nation's wealth"

For the first 25 years of its life the Institute had concentrated on external hygiene, in the next 25 it had begun to think of hygiene in the home, and sought the help of women, seeking also to have the doctrines of hygiene taught to school-children Later its influence spread to the Dominions, some of which were doing better than the mother country—for instance, he had seen how child welfare was progressing in Malaya among the quite ignorant natives, though large rooms were needed to carry on the central work, for the Malay mother always brought with her to the bureau a child, an umbrella, a basket of poultry, and her husband, all of which had to be suitably bestowed around her before she could begin accepting advice He concluded by saying that the Congress with 1800 members, and many foreign delegates, was worthy of the jubilee of the Institute, and owed its success to the work of the staff, especially for the secretary, whose labours for the Institute for 45 years had been recognised by the Patron of the Institute, the King

Returning thanks for "The Delegates," Prof A Castellani recalled the great work for tropical medicine done by Joseph Chamberlain, the father of the Minister of Health, founder of the tropical schools of Liverpool and London Dr G C Strathairn spoke as the delegate from Jamaica Sir Thomas Hughes thanked the ladies present for their attendance at the dinner, and Dr Andrew Balfour proposed the health of the Duke of Northumberland, their chairman The Duke replied that, though proverbially a reactionary, and indeed perhaps on that account, he liked to be associated with those in the forefront of advances and especially with work, like that of the Institute, which was all for the benefit of others

MEDICINE AND THE LAW

Hospital Collections Precautions against Fraud

A GROUP of defendants was charged lately with conspiring to obtain charitable contributions by fraud The prosecution alleged that they made collections at cinemas in various parts of London for the "National Hospital Aid Society," and that considerable sums were obtained, though in no single instance did any hospital or similar institution benefit Some of the defendants it was said had actually addressed the audiences in cinema halls, urging the claims of the society to public support Three young women had been engaged as collectors, but became suspicious and communicated with the police One of these gave evidence at the police-court, according to a report in the *Times*, and explained how she came to be engaged to collect She was told her remuneration would be 5*s* in the £ on what she collected, with travelling expenses She said she was told to collect from door to door and not in the streets, and she was particularly directed not to show her collecting box in the streets The defendants were convicted at the Central Criminal Court and received sentences of imprisonment With regard to street collections it may be of interest to note that the Home Office has recently made fresh regulations superseding the existing code published in September, 1923, though without making marked changes

Under present regulations those responsible for a scheme of street collection must first obtain a permit from the Commissioner of Police They must apply in writing in advance, and must state inter alia the name of the society responsible, the charity or fund, its objects, and its administrative headquarters No collection may be made except on the day and between the hours and in the districts, streets, or places named in the permit Nobody may take part unless with the written authority of the body which holds the permit of the police, this written authority must be produced on demand of a police officer Collectors must be stationary on the footway, not more than two at the same point, and not nearer than 30 yards to the next collecting point Nobody under 18 may collect Collectors must not be accompanied by animals, and must not importune anyone to his annoyance Provision against fraud is made by insisting that all collecting boxes be numbered consecutively and sealed, and that they be delivered to the persons responsible for the application of the money with the seals unbroken Within a month of the collection day the promoters must forward to the Commissioner of Police an audited statement in a prescribed form showing the details of the amount collected, the expenses and the amount distributed to the charity or fund No collector is to receive any payment by way of reward, and no promoter is to have, directly or indirectly, any payment or reward except such payments as are shown in advance on the form of application for a permit The new Home Office regulations differ from those of 1923 in that the Commissioner of Police is no longer authorised to give a permit of a continuous character if satisfied that special reasons justify the grant Nor may the Commissioner any longer authorise special exceptions to the rule that all persons acting as collectors must occupy a stationary position at some point of the footway There are a few minor changes of language, the regulation forbidding the giving of "payment or reward" to a collector, for instance, has been changed into one forbidding "payment by way of reward", it thus is now lawful to make payments to collectors otherwise than by way of reward or to reward collectors otherwise than by payment

With our system of hospitals maintained by voluntary contributions, and with the modern organisation of flag-days and flower-days, some such regulation is essential It is surprising to find that the Home Office did not possess the necessary powers until the passing of the Police, Factories, &c (Miscellaneous Provisions) Act of 1916 Precautions against fraud in hospital collections must be carefully framed and rigorously enforced The public must have no misgivings in its generosity

Death due to Overdose of Sleep-inducing Drug

In investigating a death apparently due to drug-taking, a coroner has occasionally suggested that all narcotics should be brought within the Dangerous Drugs Acts If this suggestion has been deemed a little too sweeping, there seems to be at present an unfortunate uncertainty whether or not particular drugs and preparations are within the Acts At a recent inquest evidence showed that a lady was found unconscious in an open boat, and died next day without recovering consciousness She had suffered from sleeplessness, a London practitioner had prescribed "dial" tablets for her a few months ago, and her death was clearly due to a large overdose of this hypnotic preparation Evidence was given that dial was a proprietary medicine, of the same type as veronal, and was not included in the British Pharmacopœia The foreman of the coroner's jury pertinently asked if this drug could be obtained without a doctor's certificate The witness, a medical practitioner, replied that he had never used or seen the drug himself; he believed some kind of doctor's note was necessary before it could be supplied, but he could not definitely say. An open verdict was returned It was clear that the drug was self-administered, but there was no evidence of the state of the deceased's mind No blame was or could be attached to the doctor who had prescribed this sleep-inducing drug

The Ministry of Health Committee instituted upon Morphine and Heroin Addiction dealt with the danger of a patient becoming an addict as the result of medical treatment or self-treatment for relief of physical pain caused by asthma, insomnia, overwork, anxiety, and other causes of mental distress The report contained a section on precautions in the use of the drugs in ordinary medical practice advising that the quantity supplied or ordered at one time should not ordinarily exceed what will be given before the patient is seen again The Committee further advised that the patient should not be informed of the name of the sedative employed, they thought it particularly inexpedient to hand over to the patient original packages containing morphine tablets or the like which bear on their label a clear statement of the exact amount in each tablet; and they strongly deprecated hypodermic administration of the drug by the patient to himself This excellent advice in relation to morphine and heroin addiction has a somewhat remote application to sleep-inducing preparations in cases where there is no reason to suspect or apprehend addiction If the law intends to restrict the prescription of sleep-inducing drugs by the machinery of the Dangerous Drugs Acts it must be careful to make itself clear In the recent painful incident the victim had suffered from insomnia; her health had, it seems not been so good since she lost her husband last year She went to the seaside for a change. While there she hired a boat ostensibly for a fishing expedition She took an overdose of a preparation to which a doctor had recommended her to have recourse Her act was either an accident or a deliberate impulse to take her own life No professional care can ensure that these unhappy cases will not occur.

IRELAND.

(FROM OUR OWN CORRESPONDENT)

Irish Tuberculosis Officers in England

SOME months ago the Department of Local Government and Public Health of the Irish Free State made arrangements with the Ministry of Health in London for a small number of selected county tuberculosis officers to spend a few months in public health work with medical officers of health in England, in the hope that they might thus obtain a wider outlook in public health work and some knowledge of administration methods Several of these visitors have now returned to Ireland, and have submitted reports to their local authorities They all speak in the most grateful terms of the pains taken by the Ministry of Health and by local medical officers of health to make their period of pupilage as valuable as possible Care was taken to show them the several aspects of health work in different districts, rural and urban A perusal of the reports shows moreover, that the main object of the visits to England has been gained in that the officers have returned with their imagination quickened and their outlook broadened While they have hardly had time to become familiar with the details of administrative work, they have grasped the general principles on which administration is based The courtesy shown by the Ministry of Health and the medical officers of health concerned towards our youthful health service is deserving of grateful mention

The Milk-supply in Ireland

For some time the newspapers have been drawing attention to the lack of cleanliness of the milk-supply of Dublin and other cities of Ireland The bacteriological reports of Prof J. W. Bigger, Dr. D. Houston, and others, have shown a dangerously high bacterial content and a frequency of tubercle bacilli in milk as exposed for sale The Minister of Local Government and Public Health has now appointed a committee to inquire into the question and this will consider whether the existing regulations relating to the cleanliness of milk are sufficient The medical members of the committee are Mr. Matthew J. Russell, medical officer of health of Dublin, and Deputy T. Hennessy. Both are Fellows of the Royal College of Surgeons in Ireland

Honorary Degree for Sir Berkeley Moynihan.

At the Summer Commencements in Dublin University the degree of M Ch was conferred honoris causa on Sir Berkeley Moynihan

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

New Medical Practice Act

THE State Medical Society of New York is to be congratulated on the fact that after more than a dozen years of hard work it has succeeded in securing from the legislature an amendment to the public health law in relation to the practice of medicine. Under the old law there have been no means of bringing to justice those who are not properly qualified or licensed to practise medicine, and the State has been much plagued with quacks The old law puts the responsibility of exposing such individuals upon the County Medical Board a body that was naturally disinclined to play detective and police officer. The new law makes it necessary for all physicians to register annually:—

> "Any licensed physician who fails or neglects to register by Jan. 1st of any year . shall be required to pay for registration in addition to the fee of two dollars, a further fee of one dollar for each 30 days or part thereof, that he is in default and any licensed physician who wilfully refuses or omits to register hereunder and engages in practice shall be subject to a civil penalty of one dollar for each day that such practice shall continue."

Violations of the law will come into the province of the Board of Medical Examiners, who will employ inspectors to investigate charges; they will be supported in their prosecutions by competent lawyers. Only those licensed by the Board will be allowed to practise medicine or call themselves "doctor" Osteopaths are licensed but to obtain a licence an osteopath must prove that he has studied osteopathy for not less than three years under conditions satisfactory to the regents, or if his training has been done after 1910 he must have studied for more than four years in an approved college. An osteopath is not allowed to administer drugs or to perform surgical operations which involve the use of instruments.

An interesting innovation is the provision for the formation of a committee on grievances This comprises four members nominated by the State Medical Society, two members nominated by the State Homœopathic Society, and one member nominated by the osteopaths as well as three members "of conspicuous professional standing" appointed by the regents To this professional body are addressed all complaints of unprofessional conduct The findings of the committee are passed on to the regents, in whose hands are vested disciplinary powers.

The new law should do much to raise the standards of medical practice in New York and will doubtless be a model for legislation in other States

Medical Publicity

A good deal of pressure is being put upon medical societies in this country to undertake corporate advertising. The dangers are obvious, and yet there is something to be said for meeting the noxious publicity of fraudulent vendors of patent medicines with the publicity of medical truth One of the latest societies to enter upon an extensive campaign is the Jefferson County Medical Society in the State of Texas The campaign will last a year and each week the advertisers will make use of 60 inches of space in two papers (morning and evening) with a combined circulation of about 50,000 The campaign has the approval and endorsement of the State Society In experimenting with advertising material it was found that attempts to extol the regular physician, to compare him favourably with the irregular practitioner, or to plead for payment of his bills, were not received well either by doctors or by the public The present campaign attempts to explain what medicine has done and can do for the protection and recovery of health, and the advertisements seem to be acceptable to both parties

MEDICAL INSURANCE AGENCY.

A MEETING of the committee of management of the Medical Insurance Agency was held at the House of the British Medical Association on July 9th, Sir Humphry Rolleston presiding

It was reported that Dr R A Gibbons had been selected to represent the Medical Insurance Agency on the Council of Epsom College, and he was asked to arrange a meeting between Dr Raymond Crawfurd, the chairman of the Council of the College, and Mr Bishop Harman and Mr Ferris Scott to ascertain in what way the Agency can best be of assistance to the College

Annual Report

The report of the work of the Agency during 1925 was presented by the Chairman, and showed that during the year under review steady progress had been made, and in particular, the number of life and endowment policies issued through the Agency had increased The development of the Agency, said the report, was reflected in the fact that in the past five years the premium income had been doubled while its influence in deciding as to the propriety of claims, with a view to completing satisfactory settlements was more widely recognised Life and endowment policies were issued through the Medical Insurance Agency between 1907 and 1920 to the extent of £416,684, between 1921 and 1925 the annual policies issued increased from £105,500 to £160,935, the total since the inception of the Agency now exceeding £1,000,000 The report indicated, however, that the income of the Agency from this source would not be proportionately greater each year, as a much higher rate of commission was earned on new proposals than on renewals, although the office work involved in looking after a life policy, once granted, was as great in the subsequent years as at the outset

The report showed that more proposals were received in 1925 than in any previous year for motor-car insurance with an accompanying increase in premium income, but as there is a lower premium on the Doctor's Special Policy, introduced through the Medical Insurance Agency and underwritten at Lloyd's, and as this policy is being made use of increasingly, commissions have to be calculated at a lower rate, the insured persons gaining while the Agency showed a decrease in commissions earned A decrease could also be expected, it appeared, under the heading of Employers' Liability, because more medical men were taking out a comprehensive household policy in which domestic servants were included, a gain in one place having thus to be set off against a loss in another The attention of members of the profession had been called, said the report, to the advantage of Sickness and Accident policies, a class of protection which should become more popular with the medical profession

The rebates to medical men since the formation of the Agency have exceeded £22,000, the figures for the last five years being given in the report as follows 1921, £1697; 1922, £2064, 1923, £2069, 1924, £2811, 1925, £2791.

Grants to Medical Charities

The report says · "Grants to medical charities were made during the year 1925 to the extent of 2,000 guineas, making a total since 1910 of £14,395 5s divided as follows Royal Medical Benevolent Fund, £4119 10s, Royal Medical Benevolent Guild, £4148 5s Epsom College, £3318, M I A Girls' Education, £937 10s ; Sundries, £1872

"The distributions to the charities during the past few years have been 1920, £1,015, 1921, £1,965, 1922, £1,595 ; 1923, £1,500 ; 1924, £787 10s, 1925, £2,100 Since rebates exceeding £22,300 have been returned to members of the profession and charitable contributions totalling £14,395 have been made, it may safely be contended that the Medical Insurance Agency is fulfilling successfully two of the functions for which it was formed "

The report included, also, a reference to the large amount of work now done by the Agency in assisting in the choice of policies to meet individual needs, and drew attention to the necessity to medical men not only of insurance policies, but of securing proper settlement of claims A further activity of the Agency was foreshadowed in the closing statement of the report that during the year the Agency had given careful consideration to the terms of a policy to enable medical practitioners to obtain loans from an insurance company for the purpose of partnerships or practices

The report was approved with duly audited balance sheet and accounts for the year ending Dec 31st, 1925 Arising out of the balance sheet Dr R A Gibbons and Dr R A Langdon-Down were appointed to consider the question of the rent for the accommodation received at the House of the British Medical Association and to report to the next meeting of the Committee of Management of the Agency

Five Years of Progress

The following statement of progress made during the years 1921–1925 was submitted to the meeting —

Nett Premium Income for New Insurances and Renewal Premiums for the Years 1921–1925

Class of insurance	1921	1922	1923	1924	1925
	£	£	£	£	£
Life and annuities	15,652	21,556	29,917	33,847	37,924
Increase	3,264	5,904	8,361	3,930	4,077
Motor cars	11,156	12,767	13,517	16,490	16,849
Increase	2,211	1,611	750	2,973	359
Household, fire, and burglary	1,472	1,895	2,445	2,598	2,774
Increase	98	423	550	153	176
Sickness and Accident and Workman's Compensation	1,722	1,864	1,944	2,149	2,694
Increase	126	142	80	205	545
	£	£	£	£	£
Premium income	30,002	38,082	47,823	55,084	60,241
Increase	5,699	7,934	9,741	7,261	5,157
	£	£	£	£	£
Commissions, &c	4,540	5,250	5,408	7,192	7,917

Sickness and Accident Insurance Premiums do not include the very considerable business passed to the Medical Sickness Annuity and Life Assurance Society

---

ROYALTIES FROM PASTILLES—At the Lancashire Chancery Court at Liverpool on June 23rd it was mentioned that since 1908 Liverpool charities have benefited by more than £8000 from the sale of certain throat pastilles invented by Dr John Bark, of Liverpool As a member of the medical profession, Dr Bark declined to take the profits and arranged that his share should go to medical charities, the manufacturers have paid over royalties each year The Court in a friendly action agreed to a scheme whereby the manufacturers would continue to have the rights of manufacture and sale and should pay £270 per annum—this amount to be distributed amongst Liverpool charities

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH

THE following are health statistics for 1925 from a group of boroughs, two of them county boroughs:—

Name of district.	Estimated mid-year population (R. G.)	Birth rate.	Death rates per 1000 of the population: All causes.	Tuberculosis	Cancer	Resp. diseases with influenza	Heart disease	Death-rates per 1000 births: Infant mortality	Maternal mort. from childbirth
Coventry C	133,500	16·3	10·6	1·23	1·14	1·9	1·0	77	4·6
Ealing B	68,410	14·0	10·0	0·76	1·32	1·7	1·5	56	3·1
Cambridge B	59,020	14·1	10·3	0·88	1·44	1·6	1·0	45	1·2
Wimbledom B	58,170	13·0	10·9	0·77	1·54	1·9	1·7	62	0·0
Swindon B	56,880	16·6	11·1	0·90	1·56	1·7	1·8	60	4·2
Eastbourne C B	55,060	12·0	12·1	0·87	1·71	2·1	2·2	45	—

C = City. C B = County Borough. B = Borough.
— = Not given.

Coventry

Dr. E. H. Snell quotes the Registrar-General as stating that at the last census the night population of the city was 128,157 and the day population 134,999, and that 7414 persons enumerated at Coventry worked elsewhere whilst 14,256 enumerated elsewhere worked in Coventry. During 1925 unemployment reached its lowest post-war level.

Dr. Snell thinks the effect of grading "is towards a bettering of the milk-supply." So far the only step taken in the city has been the granting of three licences for pasteurised milk, and the result of sampling has been to show that the number of organisms frequently exceeds the permissible limit. Some progress has been made towards the provision of a public abattoir, and the report reproduces a design by Mr. R. Stephen Ayling, F.R.I.B.A. With slaughter-houses scattered all over the city, as at present, it is estimated that six whole-time meat inspectors would be needed to carry out the new meat regulations.

There were 20 notifications of encephalitis lethargica, with 13 deaths, as compared with 48 notifications and 8 deaths in 1924. Coventry is largely an unvaccinated community; there were 72 cases of small-pox—most of them mild—with no deaths. Sanocrysin has been tried at the sanatorium in the treatment of pulmonary tuberculosis since the summer of 1925 with immediate results that are encouraging. A gynæcologist, Dr. A. J. Ballantyne, has been appointed to attend the antenatal centre once a month, and an average of 21 mothers per session have consulted him. Miss Barratt, the chief health visitor, reports that the long-tubed bottle has disappeared, but that habits change slowly with regard to dummy-teats. As infant protection visitor appointed by the guardians under the Children's Act, she states that during the year 45 children were on the register and that in all cases but one, where the home was not suitable and the child was removed, a high standard of efficiency was attained by the foster-mothers. The reasons given for applications for admission to maternity wards show that many married couples are living in lodgings. The scarcity of houses has also prevented the closure of unfit houses. A preliminary town-planning scheme was adopted a year ago.

In his school report, Dr. Snell points out that the visiting of the pre-school child needs to be extended and to be linked up more closely with school medical work. Arrangements have been made for the dental treatment of children of 3 to 5 years old at the school clinic, and for the record-cards of children seen at the centres to be passed on to the school clinic. There are still a certain number of parents who absolutely refuse to allow their children to wear glasses. The school dentists report that much of the benefit of the treatment given is lost through their inability, with the present staff, to treat the age-groups over 9 years. The residential open-air school at Corley Camp has accommodation for 15 boys and 15 girls. The camp is on high ground five miles from the city. Ten of the cases were sent because of rheumatism and chorea, and, as a rule, these cases did exceedingly well. Special attention has been given to chorea in the schools. The school medical staff was invited by the Board of Education to take part in special inquiries, but the staff was too small to undertake any such additional work.

Ealing

Dr. Thomas Orr reports that medical practitioners in the district have been asked to help in the education of the public concerning cancer, and to promote its early diagnosis and treatment. Every facility for scientific diagnosis and the help of consultants are available at the King Edward Memorial Hospital. During the last five years 792 houses have been built by private enterprise and 208 by the town council. The rental of the recently-built municipal houses varies from 15*s.* 6*d.* to 22*s.* 6*d.* per week and working-class people can, as a rule, only pay this by sub-letting. During 1925 the council began the erection of 250 more houses. The general standard of housing is good, but there are three small areas which are made slum-like by bad tenants. At least 80 per cent. of the milk supplied in the district is pasteurised by the "positive holder" method and bottled. A proportion of the remainder is pasteurised by the "flash" method. Dr. Orr hopes much from the proper administration, especially by county councils, of the new Milk Act and Tuberculosis Order. He points out that pasteurisation is really a confession of failure.

The meat regulations have been well carried out in Ealing, but Dr. Orr points out that protection of cooked meat from dust and flies is much more important than protection of raw meat, and he hopes that similar regulations will be made to apply to all classes of cooked meat. A gynæcologist, Dr. J. W. Bell, has been appointed for antenatal consultations and his advice or assistance is at the disposal of medical practitioners in cases of abnormal or complicated labour. The Ealing day nursery has been closed owing to the small demand. There is complete coöperation between the maternity and child welfare centre and the school clinic, and also in the arrangements made for the teaching of infant care and management to the elder girls in the schools. An outbreak of pemphigus neonatorum occurred in the maternity hospital in November, fortunately of a mild type. The hospital was closed and disinfected, but after reopening there was a recurrence and cases kept appearing up to April, 1926.

A table in the school report shows great improvement in the children's teeth since 1915, although in 1925 there was a slight set-back for which it is difficult to account. During 1925 47·8 per cent. of the entrants, 44·3 per cent. of the intermediates, and 74·0 per cent. of the leavers had sound teeth. These figures have to be compared with 23·0, 26·2, and 35·7 for the year 1915. Some parents still refuse to have their children's teeth attended to, and steps are to be taken to insist upon treatment in all but the mildest cases of dental defect. A new scheme for dealing with crippled children through the national orthopædic hospitals at Great Portland-street and Stanmore came into operation in September, 1925. Special arrangements are also made for the regular supervision of the 93 school-children found to be suffering from valvular disease of the heart.

Cambridge

Dr. Andrew J. Laird reports three accidental deaths from gas-poisoning during the year. One was due to a defective hot-water geyser and two were caused by a leak from the gas-tap in the bedroom He suggests that gas fittings should be periodically overhauled, but neither gas companies nor plumbers lay themselves out for this work If the supplying bodies had placed on them the duty of testing the fittings of their customers in return for a small fee, the latter would only have themselves to blame for disasters such as those mentioned

Mr W B Grandison, the public dental officer, refers to the difficulty of getting all the mothers to persevere with dental treatment for their children In the Cambridge scheme every effort is made to secure the healthy state of the mouths of expectant and nursing mothers and the babies are enrolled in the scheme when they have cut four teeth Mr Grandison is especially anxious that the work should continue between the ages of 3 and 5 years In 1925 172 babies were enrolled During the last six years the local authority have erected 417 houses, but the need is still very great and the number of families waiting for council houses is between 700 and 800 A Housing Week was held so that no one really interested might be ignorant of the facilities which existed for obtaining assistance to build or purchase So far there is no evidence of a movement upwards from the very lowest stratum of housing The contamination of apples by arsenic has received attention, and although arsenic was found there was no evidence of any ill-effects therefrom

Wimbledon

Wimbledon, Dr A Gilmour states, is mainly a dormitory for workers in London, and its popularity as such is responsible for the overcrowding which exists in practically all parts of the town Houses for occupation of the working-classes are not erected by private enterprise, and suitable sites for municipal schemes are not easily found There is much subletting of rooms, and Dr Gilmour suggests that this practice might be restricted by by-law to the families of those employed locally, but admits such a measure would be difficult to administer

The school report shows that dental inspections numbered 3059, and that 2418 children required and were offered treatment Of these only 1197 attended to receive it In addition to the use of the public baths by school-children for swimming, the Health Committee supplies hot baths, including soap and clean towels for school-children at the price of 1*d* Great use is made of this opportunity

Swindon

Dr Dunstan Brewer gives an interesting account of the history of Swindon, its progress in sanitary matters during the last five years, and the dangers to health (bacterial and otherwise), which threaten the Swindonians He concludes with a study of the recent behaviour of scarlet fever in his district In the early nineteenth century Swindon was a village standing on a hill of Purbeck limestone, 480 feet above sea-level In 1842, when the Great Western Railway moved its works from Wootton Basset to Swindon, the industrial town was built in the valley on the Kimeridge clay and the new buildings were congested, because it was considered essential for the workpeople to live a stone's-throw from their work There are no slums and the buildings seldom exceed two stories There is not much smoke and rickets is almost non-existent The water-supply is hard and from two sources The Wroughton source resembles a surface-water and deteriorates after the end of a drought Dr Brewer suggests that it should not be used on such occasions until it becomes normal again The Ogbourne source is less liable to pollution, and Dr Brewer proposes that the borough should purchase sufficient of the land above the adits to control the surface and prevent pollution through cracks in the chalk The condition of overcrowding does not improve much, and none but corporation houses are built for letting The man with a small wage and a large family cannot find the 10 per cent deposit for purchasing Until satisfactory property can be rented at a low figure overcrowding will remain as it is The corporation does its best to provide for the large families and has a housing estate outside the borough with 300 completed houses and 120 in course of erection There is great need for an adequate general hospital with up-to-date equipment

The municipal maternity hospital established in 1922 provided for more than one-fifth of the total confinements in 1925 A system of notifying puerperal pyrexia immediately, with a view to thorough investigation of each case, is in operation, and during the last five years no death from puerperal sepsis has been registered Serious cases of puerperal fever are removed to the Fever Hospital for treatment At the child welfare clinic several cases of an infantile affection characterised by a peculiar lemon colour, enlargement of the liver and spleen, and degeneration of the blood cells have been met with During 1925 six cases occurred, two ending fatally, the deaths were certified as due to bronchitis Another condition mentioned is abscess of the glands of the neck without tangible cause These were coincident with the epidemic prevalence of scarlet fever and measles Dr Brewer refers to unnecessary operations for circumcision, with troubles and occasional deaths following the operation, and has found that if the prepuce is freed and cleansed soon after birth the need for circumcision becomes rare. For the fourth year in succession no Swindon-born child has been blinded by ophthalmia, whereas in former years two such disasters occurred annually The report includes a careful analysis of the cause of death of infants who came under the purview of the clinic

Eastbourne

Dr W G Willoughby mentions as some of the features of 1925 an almost complete absence of diphtheria, a high death-rate from influenza, 56 per cent of the deaths being of persons over 65, and an excess of deaths over births for the first time Tuberculosis especially non-pulmonary, showed a marked decrease The number of houses built in 1925 was the largest for many a year and the promise of 1926 is better still in respect of small houses Dr Willoughby regrets the want of sympathy shown by private owners and occupiers of houses with regard to letting rooms to young mothers and those about to become mothers This difficulty is only met to some degree by the preference given to persons with children in the case of municipal houses In municipal houses subletting is constant, overcrowding occurs, and rents are frequently overdue Dr Willoughby considers the personal work by health nurses in the homes vastly more important than mass lectures at the centres Progress in food protection has been disappointing, and the new Orders have been of no practical value in the protection of meat and other food

Nineteen samples of Certified Milk were taken from two producers On six occasions the milk from one producer failed to satisfy the Ministry's standard

The hours of sunshine at Eastbourne were 1898 9, which was the seventh highest recorded for the United Kingdom

---

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 3RD, 1926

Notifications—The following cases of infectious disease were notified during the week—Small-pox, 135 (last week 165), scarlet fever, 1552, diphtheria, 855, enteric fever, 29, pneumonia, 527, puerperal fever, 46, cerebro spinal fever, 2, acute poliomyelitis, 3, acute polio encephalitis, 1, encephalitis lethargica, 52, continued fever, 1, dysentery, 11, ophthalmia neonatorum, 107 There were no cases of cholera, plague, or typhus fever notified during the week

Deaths—In the aggregate of great towns, including London, there were 3 (0) deaths from enteric fever, 25 (2) from measles, 8 (0) from scarlet fever, 30 (5) from whooping-cough, 32 (5) from diphtheria, 47 (7) from diarrhœa and enteritis under two years of age, and 28 (6) from influenza The figures in parentheses are those for London itself

REPORTS OF SCHOOL MEDICAL OFFICERS

The following table summarises the figures given in the school reports for two Scottish counties .—

Name of county	No on roll	Av elem school atten-dance	No of routine children exa mined	No of special examina tions and re-inspec tions	Percentage of children found on routine examination requiring treatment *
County of Dumbarton	28,806	23,867	7,446	2,152	13 8
County of Stirling	—†	—†	8,374	1,734	3 1

* Excluding dental defects and uncleanliness † Not given

County of Dumbarton

Dr T L Thomson presents his report as a series of statistical tables of great detail This is an excellent method of summarising results, but such a report does little to stimulate the interest and cooperation of parents and laymen; the value of enlisting public support justifies full discussion and comment

Rickets and chest diseases generally are on the decrease, but the rather high incidence of verminous children (11 5 per cent.) indicates a certain lack of parental interest and supervision, resulting in an increase of " dirt " diseases Though no details are given, it is significant that, of 2310 children treated at the minor ailment centres, 1137 had skin affections The number of parents attending the medical inspections has gradually risen from 3 per cent in 1911 to 25 6 per cent in 1925; this percentage should be greatly increased as the full knowledge of the good work being done gets disseminated The fact that only a small number of abnormal children are reported in the county (139 mentally and 52 physically defective) is perhaps largely accounted for by the difficulty of undertaking the work of such a large district where only two whole-time medical inspectors are engaged

County of Stirling

Dr T Adam reports the smooth and satisfactory working of the new scheme coordinating medical and nursing services of the county under a joint committee representing the authorities for child welfare, school medical service, and tuberculosis This system has many advantages Among them may be noted the arrangement by which all children under 5 suffering from squint are brought to the notice of the school oculist There is also good cooperation with the sanitary authority The importance of ear, nose, and throat conditions is rightly emphasised, and it is probable that services of a surgeon specialist will soon be available Good accounts are given of the work of the special schools and the merit of the teachers is recognised In the rural areas, however, provision is still lacking for mentally and physically defective children, and it is to be hoped that the difficulties in this direction will be surmounted

---

Glasgow Royal Hospital for Sick Children —The report of the directors shows a remarkable response to the appeal for £75 000 to provide urgently needed additions and extensions The whole of the money was subscribed in less than six months (without the aid of bazaars, sales of work, fêtes &c) by about 1000 persons When these works and the extension of the country branch at Drumchapel are completed, there will be 400 cots, and the directors believe that the institution will then be the largest and finest of its kind in existence

Liverpool Open-air Hospital for Children.—This hospital is at Leasowe At the annual meeting on June 21st it was stated that nearly £24,000 had been spent on improvements during the last two years, and that over £10,000 had been raised without a public appeal The senior medical officer, Dr T Hartley Martin, said that 80 per cent of the patients who were treated at Leasowe went away cured After-care of the children is an important part of the hospital's work , a small workshop for the training of ex-patients has been established and outdoor clinics have been added An appeal is being made to clear off a debt of £13,000.

NON-SPECIFIC PROTEIN INJECTIONS IN CHRONIC ARTHRITIS

To the Editor of The Lancet

Sir —The toxic material which is presumably the proximate cause of chronic articular rheumatism and fibrositis is usually regarded as being made up of proteins and their split products, albumoses and proteoses

The principle that underlies the treatment of these conditions by the introduction to the blood stream of proteins, foreign to it, is the stimulation of enzyme activity This promotes the appearance in the blood of enzymes that have the power of digesting the albumoses and proteoses formed by the acid hydrolysis of the actual proteins thus introduced To these enzymes the name " proteolytic " is given. Apart from gastro-intestinal processes, proteolysis is normally an intracellular phenomenon The possibilities of toxic effects on the organism are always present when the process takes place outside the cells to any considerable extent

What might be called the opposite process or that of ' detoxication " implies the ability of the cells or fluids of the organism concerned to digest toxic protein fragments, and this is brought about by the stimulation of enzyme activity Besides the latter phenomenon we have an increased cellular activity generally, the stimulation of the bone-marrow the mobilisation of leucocytes, and the formation of antibody Recovery eventually comes about through changes in the lymph, fluids rich in antibody being forced through the lymph channels This causes a varying amount of constitutional disturbance along with a rise in temperature

The protein may be introduced to the blood stream by means of a syringe and needle or it may be "derived" from the body itself as follows —

Stimulation of the skin by hot baths, packs, hot air and the like, produce an active hyperæmia therein This is associated with increased lymph-supply, and in consequence certain skin enzymes, such as lipase and proteose, are swept into the circulation along with exudates from the joints or fibrous tissue These combined act as antigens or stimulators of enzyme activity In other words, they act precisely as a foreign protein would In this connexion it is useful to remember that blood so slightly altered as by being drawn from one part of the body and reinjected at another is capable of setting up a reaction and really acting as an antigen to itself

This constitutional disturbance, brought about by the employment of baths and various physical measures, has been recognised at spas for centuries and is always known as the bath reaction. Patients themselves have come to expect it and look on it as a favourable sign

" Protein shock " and a " bath reaction " are fundamentally the same, whether brought about by Dr Yeoman's methods or Dr Sundell's The only thing that differs is the route

I am, Sir yours faithfully,

London, W , July 3rd, 1926 M B Ray

HÆMORRHAGE ASSOCIATED WITH PERI-TONSILLAR ABSCESS

To the Editor of The Lancet

Sir,—The publication in your issue of June 26th last, by Mr Norman Patterson of a case of serious hæmorrhage following the opening of a quinsy, has suggested to me the recording of the following case —

A male, aged 28, who had been subject to recurrent tonsillitis since childhood, was seen by me with the history of having been in bed with a quinsy for a fortnight and of having had, on the previous day, three severe attacks of hæmorrhage from the right side of the throat Examination of the throat showed a small clot adherent at the site of rupture of a peritonsillar abscess in the right side of the soft palate No further bleeding took place for two days, when another severe attack necessitated operative interference I dissected out the tonsil, under a general anæsthetic, and stitched up the tonsillar fossa Recovery was slow but uneventful

This case differs from Mr Patterson's, in that the hæmorrhage occurred after spontaneous rupture and that it was found possible to control the bleeding at the site of origin

I am, Sir, yours faithfully,
A J WRIGHT, F R C S Eng
Bristol General Hospital, July 7th, 1926

SURGICAL TREATMENT OF GASTRIC AND DUODENAL ULCERS

To the Editor of THE LANCET

SIR,—I have read with much interest Mr A J. Walton's contribution to your issue of July 10th I conclude that by simple suture of a perforating ulcer, he means suture and invagination of the ulcer Mr Walton states that " gastro-enterostomy at the time of perforation will depend upon the patient's condition, and later in his article he states that " in a large number of early cases a gastro-enterostomy can be perfectly safely performed at the first stage, but should the patient be seriously ill, simple closure should alone be performed " In all cases, whether early or otherwise, my experience has been that the patient is very ill Shock is what we are immediately confronted with It is true that the amount of shock varies, being less after a latent interval Again, the amount depends upon whether perforation has or has not followed directly upon a meal It should surely be our aim to minimise shock by reducing our operative manipulations to the full extent consistent with safety The operation for closing and invaginating the ulcer is all we can reasonably expect these patients to stand The addition of a gastro-enterostomy, however, rapidly and dexterously performed is bound to increase shock and so militate against success

Mr Walton states that he has had to operate upon 19 cases " where a simple closure has been performed elsewhere by surgeons holding similar views to Mr Ley and myself and that these patients have returned some months or years later with definite symptoms of chronic ulceration In two cases they have sought treatment for second perforation " Those of us who prefer the " simple suture " operation will be glad to note that in Mr Walton's series of recurrences it had stood the test for months and even years Nineteen cases from far and near in so large a clinic as that of Mr Walton, must surely represent a very small percentage of recurrence The shorter series of cases which were under the care of Mr Walton's first assistant in the follow-up department will be disappointing to many of us, and such results do not compare with others that have been published In my group of cases of perforation there was one instance of a man who perforated twice within 12 months Quite apart from this series I have had four cases that have been in the hands of other surgeons and have returned with active ulcer One was a man who was operated upon in New York for perforation Three had undergone gastro-enterostomy following perforation In one of these the operation was performed on account of hæmorrhage In the second I found a jejunal ulcer with stenosis of the stoma In the third case I found an active duodenal ulcer

Mr Walton can with confidence allay his suspicions about my statements My hospital cases I see regularly and private patients I hear about from time to time I quite agree that there is a percentage of cases (in my series 6 per cent) which comes back with recurring symptoms, but this is small There is always a more opportune time to perform a subsequent operation if necessary Why not wait for it ? Should it ever be my lot to be inflicted with a perforating duodenal ulcer I shall most certainly seek the conservative surgeon

I am, Sir, yours faithfully,
Bradford, July 12th, 1926 BASIL HUGHES

PARTNERSHIP SOME FACTS AND A WARNING

To the Editor of THE LANCET

SIR,—A friend of mine recently has been, in my opinion, treated in a most unusual manner over a projected partnership, and has in law apparently no redress I think, therefore, that it is only right that I should relate some of the facts of the case, as related by my friend to me, as a warning to others to avoid laying themselves open to a similar rebuff

The partners shall be called A and B and my friend X B retires and X agrees to buy, subject to certain conditions, which A agrees to No mention is made of any preliminary assistantship and X understood that A had accepted him as a partner B was about to undergo an operation and wished to arrange his affairs before he left the town so X pays up the bulk of the purchase money and signs an agreement to take over B's house

X then starts work with A as a partner and continues to do so for five weeks He is introduced to A's patients *as A's partner* X goes on the panel and *X's name is substituted for B's on the cards* A and X open a *common banking account* and steps are taken for X to take over B's *share of the lease of a common surgery* After discussion with A, X orders and has printed 2000 copies of a new joint account form A agrees to the form of *X's plate with both names on* This is bought and paid for by A

X calls on all the doctors in the town *as A's new partner*

With A's consent at the end of five weeks X goes to London to make arrangements for moving in his furniture and pays a locum in his absence On arrival in London X receives a letter from A saying that he thinks it would be a mistake to proceed further with the partnership and that B had acted hurriedly At the same time X learns that B is dangerously ill after the operation X wires for an explanation and the only one he gets is " that it is nothing personal "

X recovers his purchase money from B and has to look elsewhere for a practice When X went to join A he told all his friends that he was going into partnership with A He received a number of introductions to people in A's town and he now feels that he has suffered considerable moral damage, apart from out-of-pocket expenses and loss of time These facts should be a warning to those about to enter a partnership to see that the *partnership deed is signed before commencing work*, or else to arrange a preliminary assistantship

I am, Sir, yours faithfully,
London, W , July 1st, 1926 C GORDON-WATSON

HUDDERSFIELD INFIRMARY—Mr George Brooke, of Spring Wood Hall, has presented an installation of remedial baths to Huddersfield Infirmary at a cost of £1500 A tablet has been placed in the bath establishment recording that the gift was made " in recognition of the eminent ability and unremitting services of William Turnbull, Esq , M D , who for 60 years has held the office of physician to this infirmary "

THE NEW WESTMINSTER OPHTHALMIC HOSPITAL—The plans for the new hospital in Broad street, Bloomsbury, have now been settled and building will begin shortly There will be a casualty department close to the main entrance, and most of the ground floor will be occupied by an out-patients' waiting-hall to hold between 300 and 400 people Provision will be made for 14 paying patients in separate wards, and there will be wards for 20 women and 10 children, together with 10 beds for cataract cases The kitchens will be at the top of the building, and there will be ample technical and administrative accommodation

Obituary.

WILLIAM HOTSON CADGE O.B E, M R C S.

LIEUT COLONEL, I M.S (retd.)

Lieut -Colonel W. H Cadge, who died at Lowestoft on July 9th was the son of Christopher Goulder Cadge, and was born in 1853 His uncle was the celebrated surgeon, William Cadge of Norwich, and in many ways Colonel Cadge resembled him—particularly in his high sense of duty and unassuming generosity

Educated at Norwich Grammar School under Dr Jessup, William Cadge spent a year at the Norfolk and Norwich Hospital before going on to St George s Hospital, where he had a successful career and qualified in 1875 He passed into the Indian Medical Service and after a year at Netley went to India Though posted to the Civil Branch he volunteered for the Afghan War of 1879, and at Quetta distinguished himself by efficient and expeditious evacuation of the wounded Having proved his ability he was ordered to join Lord Roberts's forces at Cabul but was unable to get beyond Jumrood Fort in the Khyber Pass where however he found scope for his energy in attending to the large number of sick men from the victorious army Cadge himself went down with rheumatic fever and was invalided home He returned to India to take charge of the Lucknow gaol but poisoned his hand during an operation, and after a very serious illness again was sent back to England After a period in charge of Agra gaol he became civil surgeon successively at Fetegarh Aligarh, Fyzatal Barelli and Nainatal, and showed himself a skilful operating surgeon, particularly successful in the treatment of cataract and stone Among the civil population his reputation stood high and his services were in constant demand During the great famine he enhanced his reputation and was a member of the Lieut -Governor s staff

When Colonel Cadge retired from the Service on account of failing health he lived for a time at Lowestoft where his uncle was living also Finding little pleasure in idleness, he applied for the post of medical officer to the Mutford and Lothingland Board of Guardians and carried out his duties with careful efficiency During the war in spite of his age he insisted on serving, and was appointed to the Ranelagh Hospital at Ipswich, which he largely equipped out of his own means Here, from 1915 to 1918, he worked incessantly without regard to his own well-being, in recognition of which service he was afterwards decorated Notwithstanding poor health. Colonel Cadge took a great interest in local affairs, especially in the Lowestoft Hospital. He was an active and enthusiastic member of the board, and the hospital became the richer by his generosity He was a keen sportsman and, up to last year, a good shot. "But what endeared him to a very large circle of friends," writes a medical colleague, "was his courteous and loveable nature, his loyalty to his friends his great kindness, and his humility, which was, perhaps a barrier to the high place he could have obtained if he had ever desired fame and high position He was such an unassuming personality that only his friends knew of his great ability and devotion to duty"

Colonel Cadge married in 1882, Miss Flora Summers, who survives him.

DANIEL MACPHERSON TAYLOR.

M D. Glasg, D P H

Dr D M. Taylor, who died at Shelf on July 10th was born in 1868 He was educated at the University of Glasgow where he graduated in arts in 1878 and in medicine (with high commendation) four years later For many years he was in general practice in London and York, but in 1906 took the D P.H. and in 1910 went as school medical officer to Halifax, where he became especially interested in the Bermerside Open-Air School and Home After three years of school work, Dr Taylor was appointed tuberculosis officer and assistant medical officer of health to the Borough of Halifax combining these duties with residence at the Shelf Sanatorium of which he was superintendent During the war he served in Mesopotamia with the Royal Army Medical Corps and there is no doubt that his health was impaired His own experience and the loss of a son during the war, inspired in him a desire to give all possible help to the ex-Service men who came under his care As a diagnostician his assistance was greatly in demand by local practitioners who thought highly of his skill, and, though not widely known in the public health service he proved himself a most competent colleague. Unfortunately he had suffered from ill-health for some years and during 1925 had to be off duty for some months He worked again during the winter but since Easter had been confined to his bed

Dr Taylor leaves a widow, two daughters who are in the nursing profession, and a son who is still at school

Medical News.

University of Oxford —At recent examinations the following candidates satisfied the examiners in the undermentioned subjects:—

Medicine, Surgery and Obstetrics—Margaret N Jackson, Constance I Pattulo Rosa S Wordsworth C P Blacker, J C K Chilcott Albert V Clemmey, Gordon H. Crisp, C R Croft H E. Cuthbert J N. C Ford E L Fothergill, Kenneth A Hamilton William H Hudson Thomas C. Hunt J H Kennedy, David Lurie, Philip Morton, David I Rees Frederick J. Sale J de la M Savage, Thomas H Sellors Richard W. A. Simmons George P Thorold, Oliver R Tisdall and William R. Wood

Pathology—O H Lister Nancy B Ockenden, Howard W. Allen, I A. Brown, Eric N. Butler Henry E. Cuthbert, J A. Eddy J H Ferguson William B Fiddian-Green, C L Harding, Robert E. Havard, Reginald A. Hawthornthwaite Richard C Hodges George J M. Inkster, Albert P. Kingsley, Ronald G Macbeth, H E Mansell Arthur E Porritt J W Pugh, J S Rake, C R. Salkeld, and Edward M Wright

Forensic Medicine and Public Health—Rosaleen L. Graves, O H Lister Howard W Allen C Charleson Paul F Cluver, Gordon H Crisp, Henry E. Cuthbert, Walter N. Dickenson C L Harding, Richard C Hodges, William H. Hudson J H Kennedy David Lurie, P C Mallam, Philip Morton, Ripley Oddie, J. S Rake, and Thomas H Sellors

University of London —At a meeting of the Senate held on June 23rd it was resolved:—

That the Co-ordination and Developments Committee be authorised to approach the Duke of Bedford to ascertain whether and on what terms he would be prepared to negotiate the sale or lease of the land in Malet Street now occupied by the University, or of other land for the Institutions connected with the University now on the Bloomsbury site"

Lord Dawson Mr H L. Eason and Sir Holburt Waring were appointed to serve on the Academic Council for 1926–27, and Dr E Graham Little, Dr G N Pitt Sir Cuthbert Wallace Sir Holburt Waring, and Dr R A. Young were appointed to serve on the Council for External Students — The annual report of the superintendent of the Brown Animal Sanatory Institution for the year 1925 was received by the Senate and the appointment of Mr. F W Twort as superintendent of the institution was continued.—It was reported that Sir Holburt Waring had been elected chairman of the Finance Committee and Sir Wilmot Herringham chairman of the Committee of Medical Members of the Senate

William Julius Mickle Fellowship—Applications are invited for this Fellowship of the value of at least £200, which is awarded annually to the man or woman who, being resident in London and a graduate of the University, has in the opinion of the Senate done most to advance medical art or science within the preceding five years. Application must reach the Principal Officer not later than Oct 1st, 1926

Paul Philip Reillinger Prize—This prize of £30 may be awarded on Dec 3rd, 1926, for the best essay embodying the result of research work on a medical subject carried out by the candidate Candidates must be matriculated students who on June 1st were studying medicine in one of the schools of the University or graduates of the University, who on the same date were of not more than five years' standing from the date of taking their first degree, and who are or were students in such school. Essays must reach the University not later than Oct. 1st and particulars may be had from the Academic Registrar

Society of Apothecaries of London—The Rogers Prize, of the value of 150 guineas, for the best essay on the treatment of the sick poor and the preservation of the health of the poor, has been awarded by the trustees (Sir John Rose Bradford, President of the Royal College of Physicians, and Dr T Vincent Dickinson, Master of the Society of Apothecaries) to Mr Hugh J McCurrich, M S, F R C S Numerous essays, many of them of considerable merit, were received from different parts of the country and from as far afield as India and South Africa

Royal College of Surgeons of England—At a quarterly meeting of the Council held on July 8th, Sir John Bland-Sutton in the chair, Mr E W Hey Groves, Mr G Grey Turner, Mr V Warren Low, and Mr Victor Bonney, having been elected at the annual meeting of Fellows, were introduced and took their seats on the Council Mr George E Gask was appointed a member of the committee of management of the Examining Board in England in place of Mr W G Spencer, resigned—Sir Arthur Keith, Mr V Zachary Cope, Mr James E H Roberts, Mr Ernest M Cowell, Mr Arthur H Southam, Mr Bernard W Williams, and Mr John Howell Evans were elected Hunterian professors Mr Ralph St L Brockman, Dr Hildred Carlill, and Dr Alfred Piney were elected Arris and Gale lecturers Mr Clement E Shattock was elected Erasmus Wilson lecturer, and Sir Arthur Keith was elected Arnott demonstrator for the ensuing year—Sir Berkeley Moynihan, Bart, K C M G, C B, was elected president, and Sir Cuthbert Wallace and Mr Francis J Steward, vice-presidents, for the ensuing collegiate year—A letter was read from Sir John Rose Bradford chairman of the Lister Medical Committee, reporting that at a meeting of the Committee on June 3rd the Lister Medal for distinguished contributions to surgical science, with the honorarium of £500, was awarded to Prof A F von Eiselsberg, of Vienna, and that, in compliance with the conditions of the Trust, Prof von Eiselsberg had undertaken to give an address at the Royal College of Surgeons on some date in 1927 convenient to the president and Council—The Museum of the College will be closed from July 19th until Oct 1st for painting and redecoration

Licences to practise dentistry have been conferred upon 68 candidates who have passed the requisite examinations and have complied with the by-laws of the College The following are the names and dental schools of the successful candidates, viz —

L C Abrahams, London, A M M Anderson, Bristol G Baker Durham, A G Batten, Bristol, R G Beck, Middlesex, A Bendelstein, London M Berman, Guy's, J H Bernstein, London, R Bliden and R V Bradlaw, Guy's, A F Brazenor, London, S Brett, Charing Cross, H Brindle, Royal Dental C E Brittan Guy's, N S S Brooks, Manchester, H Brown and I E Brown, Guy's, E M Buckley, Royal Dental, I E Buxton, O St L Campion, and J W S Coe, Guy's J E Curnock, Charing Cross, R Cutler, Guy's C I Davies, London, A M Davis, Royal Dental, W N Farrar, G Fellows Smith, A W Francis, and M Gerson, Guy's, A E Gordon, London, J W Hampton and Gladys M Harwood, Royal Dental, A H B Heesom and K T Hops, Guy's, A Joffe, London, G N R Jones, Guy's, O M S Jones, Bristol, S L Kaplan, Charing Cross, R. DIPLOMA IN PUBLIC HEALTH

Part I—Pauline K O Flanagan,
Part II—Anna J O Reilly and Mary B Quinn.

UNIVERSITY OF SHEFFIELD —Mr Denton Guest, M.B, was on July 9th appointed to the combined post of demonstrator in pathology and assistant pathologist to the Royal Infirmary.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.—The Prince of Wales will open the Nurses' Home on Thursday, July 22nd, at 2 30 P.M.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —On Monday, July 19th, at 3 P.M., Mr Letchworth will give a special demonstration in clinical ophthalmology at the Royal Eye Hospital; this will be free to all members of the medical profession. An intensive course in medicine, surgery, and the specialties will be held at the Prince of Wales's General Hospital (North-East London Post-Graduate College), Tottenham, N, from July 19th to 31st, daily from 10 30 A.M. to 5 30 P.M. It will include demonstrations, operations, general hospital clinics, clinical lectures, and the practice of clinical laboratory methods From July 19th to August 12th, at 5 P.M. daily, the West End Hospital for Nervous Diseases is to hold a course of lectures on the diagnosis and treatment of common diseases of the nervous system, clinical demonstrations will be included. During August courses will be given at the Queen Mary's Hospital for the East End Stratford (August 23rd to Sept. 4th) in medicine, surgery, and the specialties, and at the Queen's Hospital for Children, Hackney-road London (August 18th to 28th), in diseases of children. Both these courses will last all day Practical courses in anæsthetics are arranged at any time to suit post-graduates and usually last about three weeks Weekly practical courses in obstetrics and child welfare are arranged at the City of London Maternity Hospital (fee £2 2*s*) Personal application must be made at the Fellowship offices Copies of all syllabuses, of the *Post-Graduate Medical Journal*, and of the General Course programme may be had on application to the Secretary of the Fellowship at 1, Wimpole-street, London, W 1.

MRS Stanley Baldwin last week laid the foundation stone of the new West London Hospital Chapel

THE Twickenham Urban District Council has received a charter of incorporation, and Dr. J R Leeson has been elected the first mayor of the new borough.

AN EDINBURGH WAITING-LIST —On July 1st the waiting-list of Edinburgh Royal Infirmary was 2469, the largest on record

WEST END HOSPITAL FOR NERVOUS DISEASES —The annual report of this hospital at Gloucester-gate, Regent's Park, records that two extra clinic rooms have been provided in the out-patient department, one of which is devoted to psychotherapy.

HOSPITAL ACCOMMODATION AT SWINDON.—There has long been a serious difficulty about hospital accommodation at Swindon and the town council has just made purchases of land as sites for a general hospital and a maternity and infant hospital.

DONATIONS AND BEQUESTS —Mr William Shaw of Holywood co Down, gave £1000 to the Royal Victoria Hospital Belfast to endow a ward to be called "The Shaw Holywood" Ward —Miss Rose Emily Boden of Whittington, Lichfield, left £1000 to the Derbyshire Royal Infirmary

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—When the foundation-stone of the new school was laid by the Minister of Health on July 7th a message of cordial greeting and renewed acknowledgments was despatched to the Trustees of the Rockefeller Foundation. The Minister announced that he was appointing a committee to report to him on the permanent hospital facilities needed by the School Sir Alfred Mond (chairman of the board of management) said that during his own period of office as Minister of Health the Trustees of the Rockefeller Foundation had made their magnificent offer of $2,000,000 for the building and equipment of a school of hygiene It had been necessary to consult the Chancellor of the Exchequer of the day upon a condition of the offer that the British Government should make themselves responsible for the maintenance of the School after it was built The necessary undertaking was forthcoming In acknowledging the help received from the Senate of the University of London Sir Alfred Mond cordially acknowledged the debt which the School owed to Sir Cooper Perry Mr Ormsby-Gore (Under-Secretary for the Colonies) spoke of the relation to the Dominions and Colonies of the tropical division of the School of which he could not exaggerate the importance In British tropical possessions the mortality and sickness rates in many areas were at present appalling If men and women trained to deal with diseases and still more with the causes of these diseases could be got to work there the problems could be solved with comparative ease Mr Neville Chamberlain (the Minister of Health) said that although the diagnosis and treatment of tropical diseases must remain in the domain of the specialist, the establishment of this School was a recognition of the fact that tropical medicine and hygiene had now become merged in a wider conception of preventive medicine The Athlone Committee had recommended in 1921 that post-graduate instruction in all branches of public health and hygiene should be concentrated at one institution which should be an affiliated school of the London University and should have a much wider scope than the training of medical officers of health for the home and colonial services The Athlone report fortunately gave expression to ideas which the Rockefeller Trustees had for some time had in mind, and they had accepted that report as an appropriate interpretation of what could be carried out in this country The general lines of the curriculum afforded some indication of the very wide scope of the proposed activities of the School They embraced physiology as applied to hygiene chemistry and biochemistry, bacteriology and immunology, medical biology (this division would absorb the greater part of the work of the old London School of Tropical Medicine); epidemiology and vital statistics and finally the group of subjects comprising the practice and principles of sanitary administration and public health The ceremony marked the beginning of a building which was the result of a combination of the two great English-speaking nations and which was probably destined to be famous as the greatest centre in the world of research and instruction in one of the most beneficent of all activities for the human race.

In connexion with the foundation of this School, its Director, Dr Andrew Balfour, who has already done so much work in its organisation, is to receive a presentation at 5 30 P.M. on July 23rd in the library of the temporary premises of the School at 23, Endsleigh-gardens, N W.

Society of Apothecaries of London —The Rogers Prize, of the value of 150 guineas, for the best essay on the treatment of the sick poor and the preservation of the health of the poor, has been awarded by the trustees (Sir John Rose Bradford, President of the Royal College of Physicians, and Dr T Vincent Dickinson, Master of the Society of Apothecaries) to Mr Hugh J McCurrich M S, F R C S Numerous essays, many of them of considerable merit, were received from different parts of the country and from as far afield as India and South Africa

Royal College of Surgeons of England —At a quarterly meeting of the Council, held on July 8th, Sir John Bland-Sutton in the chair, Mr E W Hey Groves, Mr G Grey Turner, Mr V Warren Low, and Mr Victor Bonney, having been elected at the annual meeting of Fellows, were introduced and took their seats on the Council Mr George E Gask was appointed a member of the committee of management of the Examining Board in England in place of Mr W G Spencer, resigned —Sir Arthur Keith, Mr V Zachary Cope, Mr James E H Roberts Mr Ernest M Cowell, Mr Arthur H Southam, Mr Bernard W Williams, and Mr John Howell Evans were elected Hunterian professors Mr Ralph St L Brockman, Dr Hildred Carlill, and Dr Alfred Piney were elected Arris and Gale lecturers Mr Clement E Shattock was elected Erasmus Wilson lecturer, and Sir Arthur Keith was elected Arnott demonstrator for the ensuing year —Sir Berkeley Moynihan, Bart, K C M G, C B, was elected president, and Sir Cuthbert Wallace and Mr Francis J Steward, vice-presidents, for the ensuing collegiate year —A letter was read from Sir John Rose Bradford, chairman of the Lister Medical Committee, reporting that at a meeting of the Committee on June 3rd the Lister Medal for distinguished contributions to surgical science, with the honorarium of £500, was awarded to Prof A F von Eiselsberg, of Vienna, and that, in compliance with the conditions of the Trust, Prof von Eiselsberg had undertaken to give an address at the Royal College of Surgeons on some date in 1927 convenient to the president and Council —The Museum of the College will be closed from July 19th until Oct 1st for painting and redecoration

Licences to practise dentistry have been conferred upon 68 candidates who have passed the requisite examinations and have complied with the by-laws of the College The following are the names and dental schools of the successful candidates, viz —

L C Abrahams, London, A M M. Anderson, Bristol G Baker Durham A G Batten, Bristol, R G Beck, Middlesex, A Bendelstein, London, M Berman, Guy's, J H Bernstein, London, R Bliden and R V Bradlaw, Guy's, A F Brazenor, London, S Brett, Charing Cross, H Brindle, Royal Dental C E Brittan, Guy's, N S S Brooks, Manchester, H Brown and I E Brown, Guy's, E M Buckley, Royal Dental, I E Buxton, O St L Campion and J W S Coe, Guy's J E. Curnock, Charing Cross, R Cutler, Guy's C I Davies, London, A M Davis, Royal Dental, W N Farrar, G Fellows Smith, A. W Francis, and M Gerson Guy's, A E Gordon, London, J W Hampton and Gladys M Harwood, Royal Dental, A H B Heesom and K T Hops, Guy's, A Joffe, London, G N R Jones, Guy's, O M S Jones, Bristol, S L Kaplan, Charing Cross, R F Keet, Guy's, D W Lamb, Univ Coll, G N Lewin and C E Long, Guy's, C Maude, Leeds, A S Moore and W H Naylor Guy's, Marjorie A Newland Royal Dental, J N Noriskin, London G W Oliphant, Guy's, H V Pell, Royal Dental, V C Penberthy, Guy's, E J Perks, Royal Dental, P Perl, Middlesex, C A Pollard and F Popper, Guy's, F H M Preston, K E Rispin, and H F Ritson, Royal Dental, S A Romain, London, R. Y Simpson, Bristol, H N Squire, King's Coll, N v Zyl Smit, Guy's, H B Smith, Bristol, C L Steyn and R G Swiss, Guy's, Catherine Watterson, Univ Coll, R G Wheeler, London, J White, Guy's, and A P J Williams, Univ Coll

The diploma of Member was conferred upon Alison Marianne Clark, Royal Free and St Mary's Hospitals

University of Liverpool —At recent examinations the following candidates were successful —

Degree of M D

R G Cooke and C W Healey

Degrees of M B and Ch B (Honours)

Class I —*†R G Walmsley
Class II —‡R M Ainsworth, † J F Galloway, *F Murgatroyd

* Distinction in Medicine † Distinction in Midwifery
‡ Distinction in Surgery

Final Examination for Degrees of M B and Ch B

Part III —Grace A. Austin, B Brickman, G E Church, J L Clegg, D Cohen, R. F Corlett, J C Edwards, Elinor M Gelling, E H Glynn, A J Goss, Dorothy A Gough, J Halton, D G Henry, B S Jarvis, T A Jermy, A N Jones, C Kaufman, G T Krajewski, J S Logan, D B Macaulay, W A McCurdy, J C McFarland, G McLoughlin, J Morgan, G W Paton, H E Pearson, Mary T Penrice, D E P Pritchard, A V Russell, M R Sheridan, Mary A Silcock, N P Slade, I Thomas, G D Thompson, J E Wallace, Kathleen M Ward, A K Wilson, Nora M Wilson

Part II —S W Adler, A B Anderson, T Blezard *W S Brindle, H C Calvey A N Cameron *†J K Cameron, S Canter, E Cohen, F R Craddock, W S Creer, A Dala, A Dodd, T L Dowell, W J Eastwood, Lilian W Edwards, Ruth M Fennell, J J Graham, Elsie A. Griffiths, G T Harris, *E D Irvine, K Jilani, R. N Johnson, O V Jones, I Kossew, *†T Lasker, Theresa J Lee, J L. Lewis, F E Lomas, J McHugh, T C Newman J Pasvolsky, J W Pickup E E Prebble, C Rigby, N W Riley, G L Roberts, J B Rushton, †M Silverstone V J M. Taylor, J P Thomas, S L Tunnicliffe, A. J Walsh, E N Wardle, P H Whitaker, A L Williams, and R L Wynne

* With distinction in Public Health
† With distinction in Forensic Medicine and Toxicology

Part I —J G Hattingh, R E Jackson, G W Phillips, and J Williamson

Diploma in Public Health —W E Haigh, J E Power, J A Scott, and A E Wall

Diploma in Tropical Hygiene —W J Aitken, N Bligh-Peacock, T Cullen, E G A Don, H P Fowler, D Lennox, A G Mackay, F Oppenheimer, S A. Talib, and N S Turnbull

University of Durham —At Convocations held on June 29th and 30th the following medical degrees were conferred —

Doctor of Medicine —Ram Mansoor (*in absentia*), James H Saint (*in absentia*), Margaret Scoresby Jackson, Thomas H. Blench, Charles R Smith, and Edward A Welsh

Doctor of Medicine for Practitioners of 15 Years' Standing —Vincent P Norman

Bachelor of Medicine and Bachelor of Surgery —William B Allan, Max Coll, Dorothy E Crisp, Mabel Dodds, Jessie S Dunlop, William L Fulthorpe, Hugh Gass, Dorothy Hopkinson, James H Horsley, Grace C Howie, Daniel S Jackson, Ernest E Kendall, Kenneth A W Law, John A Livingston, Graeme M Macintyre, Grace E McVitie, Alexander D Miller, Hyman Moross, Myer A Phillips, Mabel Popham, Raymond H Robinson, Henry Rosenbloom, Phyllis Routledge, Reginald C F Smith, Moses M. Suzman, Charlotte M Thomson, Robert Y Carter Arthur D W Cooke, Francis P Forrest, Hugh D Golder, Richard A Goodall, Charles V Harrison, Francis McGuckin, Sidney McD Selby, and Frank G Sinclair

Bachelor of Hygiene —Madge Hopper and George Wilson.

The following received the Diploma in Public Health (D P H) —

Madge Hopper and George Wilson

The following received the Licence in Dental Surgery (L D S) —

John Chalmers, George G Clark, Philip W Eddy, Godfrey E Hutchinson Alexander J Munro, Henry R Myers, and Charles H Richardson

Victoria University of Manchester —At recent examinations the following candidates were successful —

Final M B and Ch.B Examination

* † Kathleen Sheehan (First class Honours) J K Anderson, Florence Whitrow (Second class Honours), George Bridge J F Frank Appleton, Florence M Blades, T K Clifford, Joseph Caithness, Marguerite E Cliff, Alec Fleming, Crowther, Harriet M Dick, Margaret Dyson, E St G Gilmore, F S I H Freedlander, C F Garfit, H B Kilroe, J H Hawkins, †Fanny Howe, T J Kay, Richard Pendle-Kitson, †C T Mills, G S de W Moll, Maurice Sheehan, bury, Marjorie Reekie, C. D Roff, E J Warburton, Olive de la W Turner, W C D Walmsley, and J T Whitley

* Distinction in Medicine
† Distinction in Forensic Medicine

Forensic Medicine, Hygiene, and Preventive Medicine —Lillie M Burton, Joseph Parness, and Mary I Prentice

Hygiene and Preventive Medicine —Pieter Bester, R H Blackburn G W Jones, B R Sandiford, W S Slater, and G R Walker

Obstetrics and Surgery —R H Barnes, Helen G M Bennett, Soloman Bernstein, J W Brooks, Louie J Burton, J F Caithness H V Crabtree, Harriet M Dick, Margaret Dyson, Ralph Edmondson, Margaret Egan, Ernest Firth, I H Freedlander, J S Goller, Ernest Heard, Fanny Howe, E P Johnson, J H Kitson, George Metcalfe, G L Normington, R H Poyser, I M Preston, Marjorie Reekie, Nora Ridehalgh, C D Roff, R F Sheppard, Donald Starr, Florence V Stephen, C E Sykes, and R T Wimmer

Obstetrics —Leonard Rosenthal

Third Examination for M B and Ch B Degrees

Pathology —Leslie Bold H J Brennan, Mary G Davies, G B Hardman, Morris Levine, Kathleen McGowan, Mary E P Mackay, S L Rowley, and Henry Tickle

Pharmacology —M M Barritt ‡G L Brown, Alice M Butterworth, Alexandra W Groves, W S Ramsden, Marian M Reekie, G F Rowbotham, J F Wilkinson, and Frederick Wraith

‡ Distinction in Pharmacology

Diploma in Public Health.

Gladys F A. McLean

Diploma in Bacteriology.

A F. Abbassi and M A Omar

UNIVERSITY OF ABERDEEN—At the Graduation ceremony held on July 9th the following degrees were conferred —

DOCTOR OF MEDICINE

*John Fiddes, † William Buchan, † John S Taylor, Wallace J Gill, and Charles Shearer

* Awarded highest honours for thesis
† Awarded honours for thesis

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY

Charles Anderson, James G Bremner Charles H Cave, *Harry D Christie, Charles C Connochie, James Coutts, Archibald N Forsyth, John W Foster, John L Gammie, Douglas J T Glennie Evelyn Goldie, James R W Hay, Robert W Hendry *William J Hogg, Reginald A M Humphrey, Frederick Hunter, George P Middleton, Alexander Paterson, Catherine Peat Margaret S M Reid, Charles E Saunders Andrew D Sinclair James I Smith, *George Stephen, Arthur J W Wilkins, and Alexander Wood

* Completed Final Examination with distinction

UNIVERSITY OF DUBLIN SCHOOL OF PHYSIC, TRINITY COLLEGE.—At recent examinations the following candidates were successful .—

FINAL MEDICAL EXAMINATION

Part I, *Materia Medica and Therapeutics*, *Medical Jurisprudence and Hygiene Pathology and Bacteriology*—*T J Millin *Cecil P Martin, William J E Jessop, Dermot F Walsh, Henry R F Tweedy, Gordon W F Pratt, Thomas J O'Reilly Richard F W K Allen, Francis O W A Mahon-Daly, Julius Sayers, Harold S North, Alexander J Burden, and Samuel B Dalrymple
Part II, *Medicine*—*Gilbert T L Archer, *Victor St G Vaughan, Robert E Hadden, Herbert A Brittain, James F MacMahon, Annette K Wood Martin John J O'Dwyer, Arthur N B Odbert, Douglas Bluett, Stella C Ross, Albert Sachs, Henry M Nevin George E Dodds Lionel B Somerville Large, Gladys L Craig, Herbert Nelson George S Gardner Victor G Horan, Robert C U Warrington, and Daniel A O'C Quinlan

Midwifery—*Robert R Woods *Solomon Behr, *Robert A Q O'Meara *Wilhelm F Knobel, Edmund P N M Early, Edward G Montgomery, Joseph A Kevin FitzGerald, Evelyn E Connolly, Maiben A W Roberts, Christiaan de Wet Meintjes Ralph W T J Stewart, Gerald S Smyth, Gerald N Taylor, Edward A Ellis, and Herbert Nelson

DIPLOMA IN PUBLIC HEALTH.

Part I—Pauline K O Flanagan
Part II—Anna J O'Reilly and Mary B Quinn

UNIVERSITY OF SHEFFIELD—Mr Denton Guest, M B, was on July 9th appointed to the combined post of demonstrator in pathology and assistant pathologist to the Royal Infirmary

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR—The Prince of Wales will open the Nurses' Home on Thursday, July 22nd, at 2 30 P M.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION—On Monday, July 19th, at 3 P M., Mr Letchworth will give a special demonstration in clinical ophthalmology at the Royal Eye Hospital, this will be free to all members of the medical profession. An intensive course in medicine, surgery, and the specialties will be held at the Prince of Wales s General Hospital (North-East London Post-Graduate College), Tottenham, N, from July 19th to 31st, daily from 10 30 A.M. to 5 30 P M. It will include demonstrations, operations, general hospital clinics, clinical lectures, and the practice of clinical laboratory methods From July 19th to August 12th, at 5 P M daily, the West End Hospital for Nervous Diseases is to hold a course of lectures on the diagnosis and treatment of common diseases of the nervous system, clinical demonstrations will be included During August courses will be given at the Queen Mary's Hospital for the East End, Stratford (August 23rd to Sept 4th) in medicine, surgery, and the specialties, and at the Queen's Hospital for Children, Hackney-road, London (August 18th to 28th), in diseases of children. Both these courses will last all day Practical courses in anæsthetics are arranged at any time to suit post-graduates and usually last about three weeks Weekly practical courses in obstetrics and child welfare are arranged at the City of London Maternity Hospital (fee £2 2s) Personal application must be made at the Fellowship offices Copies of all syllabuses, of the *Post-Graduate Medical Journal*, and of the General Course programme may be had on application to the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

MR Stanley Baldwin last week laid the foundation stone of the new West London Hospital Chapel

THE Twickenham Urban District Council has received a charter of incorporation and Dr J R Leeson has been elected the first mayor of the new borough

AN EDINBURGH WAITING-LIST—On July 1st the waiting-list of Edinburgh Royal Infirmary was 2169, the largest on record

WEST END HOSPITAL FOR NERVOUS DISEASES—The annual report of this hospital at Gloucester-gate, Regent's Park, records that two extra clinic rooms have been provided in the out-patient department, one of which is devoted to psychotherapy

HOSPITAL ACCOMMODATION AT SWINDON—There has long been a serious difficulty about hospital accommodation at Swindon and the town council has just made purchases of land as sites for a general hospital and a maternity and infant hospital

DONATIONS AND BEQUESTS—Mr William Shaw, of Holywood co Down, gave £1000 to the Royal Victoria Hospital, Belfast to endow a ward to be called "The Shaw Holywood" Ward —Miss Rose Emily Boden of Whittington, Lichfield, left £1000 to the Derbyshire Royal Infirmary

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—When the foundation-stone of the new school was laid by the Minister of Health on July 7th a message of cordial greeting and renewed acknowledgments was despatched to the Trustees of the Rockefeller Foundation The Minister announced that he was appointing a committee to report to him on the permanent hospital facilities needed by the School Sir Alfred Mond (chairman of the board of management) said that during his own period of office as Minister of Health the Trustees of the Rockefeller Foundation had made their magnificent offer of $2,000,000 for the building and equipment of a school of hygiene It had been necessary to consult the Chancellor of the Exchequer of the day upon a condition of the offer that the British Government should make themselves responsible for the maintenance of the School after it was built. The necessary undertaking was forthcoming In acknowledging the help received from the Senate of the University of London, Sir Alfred Mond cordially acknowledged the debt which the School owed to Sir Cooper Perry Mr Ormsby-Gore (Under-Secretary for the Colonies) spoke of the relation to the Dominions and Colonies of the tropical division of the School, of which he could not exaggerate the importance In British tropical possessions the mortality and sickness rates in many areas were at present appalling If men and women trained to deal with diseases, and still more with the causes of these diseases, could be got to work there the problems could be solved with comparative ease Mr Neville Chamberlain (the Minister of Health) said that although the diagnosis and treatment of tropical diseases must remain in the domain of the specialist, the establishment of this School was a recognition of the fact that tropical medicine and hygiene had now become merged in a wider conception of preventive medicine The Athlone Committee had recommended in 1921 that post-graduate instruction in all branches of public health and hygiene should be concentrated at one institution, which should be an affiliated school of the London University and should have a much wider scope than the training of medical officers of health for the home and colonial services The Athlone report fortunately gave expression to ideas which the Rockefeller Trustees had for some time had in mind and they had accepted that report as an appropriate interpretation of what could be carried out in this country The general lines of the curriculum afforded some indication of the very wide scope of the proposed activities of the School They embraced physiology as applied to hygiene chemistry and biochemistry, bacteriology and immunology, medical biology (this division would absorb the greater part of the work of the old London School of Tropical Medicine), epidemiology and vital statistics, and finally, the group of subjects comprising the practice and principles of sanitary administration and public health The ceremony marked the beginning of a building which was the result of a combination of the two great English-speaking nations and which was probably destined to be famous as the greatest centre in the world of research and instruction in one of the most beneficent of all activities for the human race

In connexion with the foundation of this School, its Director, Dr Andrew Balfour, who has already done so much work in its organisation, is to receive a presentation at 5 30 P M. on July 23rd in the library of the temporary premises of the School at 23, Endsleigh-gardens, N W.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Bethlem Hospital Bill

THE Bethlem Hospital Bill, which has passed through the House of Lords, was read a third time

HOUSE OF LORDS

THURSDAY, JULY 8TH

University of London Bill

The House went into Committee on the University of London Bill, the Earl of **DONOUGHMORE** in the chair

Clause 7 (Provisions as to incorporation of colleges and schools in the University) provides as follows —

(1) No statute made under this Act shall alter the incorporation in the University of the colleges known respectively as University of London, University College, and University of London, King's College, or the vesting, disposition, or management of any emoluments, endowments, trusts, foundations, gifts offices, or institutions in or connected with either of those colleges so far as those matters are or have been regulated respectively by or under the University College, London (Transfer) Act 1905, or the King's College, London (Transfer) Act, 1908, and no such statute shall provide for the incorporation in the University of any school of the University or other college, school, or institution, but if at any time it is agreed between the University and the governing body of either of the first mentioned colleges that it is expedient that as respects that college any such alteration as aforesaid should be made, or if at any time it is agreed between the University and the governing body of any school of the University or other college, school or institution that it is expedient that provision should be made for the incorporation thereof in the University, then, in any such case, it shall be lawful for the University and the governing body jointly to make application to His Majesty in Council for a charter in that behalf, and any charter which His Majesty in Council is pleased to grant upon any such application shall have full effect notwithstanding anything in any Act of Parliament or in any previous charter, deed, or other instrument whatsoever

Earl **BEAUCHAMP** moved after Subsection (1) to insert the following new subsection —

(2) Provided always that no Statute may be made under this Bill affecting any institution which was existing on Jan 1st, 1925, except with the consent of its governing body

He said that on the second reading the Earl of Balfour was good enough to say that he would consider this point, and the amendment had been put down with a view to carrying out his wishes The amendment would exclude existing colleges from the operation of the Bill He hoped that the Government would accept it

Lord **ASKWITH** supported the amendment The Bill was founded on the report of the Committee which dealt with the University as a whole and also in certain respects with the incorporated colleges and schools Clause 7 dealt with certain colleges of the University and said that statutes affecting them should not be altered at all That was perfectly reasonable If any statutes were to be altered it should only be by agreement with the particular colleges The clause provided that new colleges ought only be incorporated by agreement In Clause 4 there was a provision concerning existing colleges, but that clause was confined to cases where statutes were made not being statutes of the University There seemed, therefore, to be a gap

The Earl of **BALFOUR**, Lord President of the Council, said that the powers given to the University of making conditions with regard to these matters were distinctly excluded with regard to existing schools Where, then, was the danger against which the noble earl wished to guard? If it was really felt that with regard to the future of the colleges or with regard to any of the present colleges some safeguard in regard to religion was required His Majesty's Government had no objection to it The whole object of this Bill was to improve the position of the constituent bodies They did the teaching work of the University and it was their prosperity which was chiefly necessary if the internal side of the University was to carry out the functions which they all desired to see it exercise The notion that they were going to reform the University without in any way affecting the constituent colleges was evidently illusory In these circumstances he felt sure that the noble earl would not press his amendment in its present form

Viscount **HALDANE** said that he entirely agreed with what the Earl of Balfour had said The amendment would paralyse the work of the Commissioners and make it impossible for them to do a number of things for which they were looking It would be infinitely better to take the Bill as it stood, which restricted the powers of the Commissioners to the substance of the plan in the report and enabled them to survey the whole field and to deal with it in the only way in which it could be dealt with As to what outside colleges should come in, that was a question only to be decided by the Commissioners after examining the evidence

The amendment was by leave withdrawn, and the Bill passed through Committee and was reported to the House

HOUSE OF COMMONS

THURSDAY, JULY 8TH

Progress of Housing in England and Wales

Mr **HERBERT WILLIAMS** asked the Minister of Health if he was now in a position to state the total number of houses completed in England and Wales in the 12 months ended March 31st, 1926 —Mr **NEVILLE CHAMBERLAIN** replied The total number of houses completed in England and Wales during the year ended March 31st, 1926, was 173,426—106,987 with State assistance and 66,439 without State assistance

Registration of Manipulative Practitioners

Colonel **DAY** asked the Minister of Health if would consider an inquiry into manipulative surgery with a view to the recognition and registration of manipulative practitioners —Mr **NEVILLE CHAMBERLAIN** replied No, Sir This question was fully discussed in the debate on Feb 9th on the motion of the hon Member for London University and I have nothing to add to the statement which I then made

Appointment of a Lay Member of the G M C

Mr **ERSKINE** asked the Vice-Chamberlain of the Household, as representing the Lord President of the Council what was the object in appointing a lay member on the General Medical Council —Major **HENNESSY** replied It would be contrary to practice to disclose the grounds upon which the Privy Council advised His Majesty to make the recent appointment No doubt my hon friend is acquainted with public discussion which has taken place in connexion with the constitution of the General Medical Council

Sir N **GRATTAN DOYLE** asked whether the appointment of a lay member signified any change of policy from that adopted by the General Medical Council in regard to Dr Axham.—Major **HENNESSY** I cannot answer that question, but I do not think so

Mr **ERSKINE** Is the hon and gallant gentleman aware that Dr Cowie, a registered practitioner, was now acting in the same capacity as Dr Axham had acted in times gone by to Mr (now Sir H) Barker

The **SPEAKER** said that seemed to involve individuals and might carry some implication which was not plain to him at the moment For that reason he would like to see the question in writing before it was put

Mr **MACQUISTEN** asked if it was not the case that the appointment of a lay member on the General Medical Council was to abate the autocracy of the medical profession and to dilute the fanatical trade unionism with which they were obsessed?

The **SPEAKER** said that the hon. Member must try to abate some of his adjectives

MONDAY, JULY 12TH

Medical Inspection of Maternity Homes

Mr **PENNY** asked the Minister of Health whether, in view of the inability of nursing association committees to deal with the technical side of their activities, he would introduce legislation enforcing the composition of an advisory committee of local medical men in all cases in addition to the regulations for inspection now in force —Sir **KINGSLEY WOOD** replied It is clearly desirable that a nursing association which undertakes the management of an institution such as a maternity home should have the benefit of medical advice, but my right hon friend doubts whether it would be expedient to attempt to enforce, by legislation, such a condition as my hon friend suggests

Mr **PENNY** asked if the hon gentleman would consider any alternative way of doing this As these institutions were to a very large extent local institutions, would it not be better if local medical men inspected them periodically?

Sir K **WOOD** My right hon friend, as the hon Member knows, has already made various suggestions with regard to this particular case, with a view to improvement, and if my hon friend has any suggestion to make I have no doubt that he will consider it

External Degrees at London University

Mr **HORE-BELISHA** asked the President of the Board of Education whether the Government proposed to take steps by legislation to set up a statutory commission to give effect to the report of the Departmental Committee on London University, which would favour the abolishing of the external degrees of that University —Lord E **PERCY** replied The Government have introduced a Bill in another place to set up a Statutory Commission to give effect to the recommendations of the Departmental Committee But if the hon Member will look at paragraph 8 of the Committee's report he will see that it is explicitly stated that none of their recommendations is in any way designed to restrict the present facilities available for external students, or to prevent their development This statement corresponds with the views of the Government and it will be the duty of the Statutory Commission under the Bill to carry out the Committee's intentions in this matter

Infectious Illness among Members of the O T C

Mr RENNIE SMITH asked the Secretary of State for War if he could give an analysis of the infectious illness of 3660 members of the junior division of the Officers' Training Corps who were for this reason prevented from attending camp in 1925 —Sir L WORTHINGTON-EVANS There are no records in possession of the department from which the desired information could be furnished as the boys in question did not attend camp I might add that it would be erroneous to assume that the 3660 members in question were ill. The great majority were "contacts" who are not allowed to attend camp owing to the risk of spreading infection

TUESDAY, JULY 13TH

PROGRESS OF PUBLIC HEALTH

The House went into Committee of Supply on the Ministry of Health vote, Mr J F HOPE in the chair

On a vote of £18 117 048 for the salaries and expenses of the Department and other expenses in connexion with housing grants to local authorities for public health services, National Health Insurance administration, &c

Mr NEVILLE CHAMBERLAIN (Minister of Health) said that cancer was increasing at an alarming rate Last year in this country, 1336 deaths from cancer occurred per 1 000,000, which was equivalent in our population to the death of 50,000 persons It had been estimated that out of every seven persons in this country who reached the age of 30 one would die of cancer It was important that the public should be educated so that the disease could be treated in its early stages The significance of the discovery of Dr Gye and Mr Barnard was that cancer was due to a virus which entered the body from outside, but which did not produce cancer until it was associated in the body with some other factor, the nature of which had not yet been clearly ascertained The right hon gentleman directed the attention of local authorities to the experiment which was being carried out at Papworth, near Cambridge, by Dr Varrier-Jones in regard to the after treatment of tuberculosis Here, he said, was a chance for one of our big progressive local authorities to start a settlement of its own on Papworth lines Dealing with small-pox, Mr Chamberlain stated that the disease was rapidly increasing in this country The number of cases were as follows —In 1922, 973, 1923, 2500, 1024 3800, 1025, 5300, and in the first six months of this year, 5500 cases This increase could not be regarded without a great deal of anxiety It was true that at the present time the disease was present in a very mild form, but in the past they had had this mild form coexisting with a form which was one of the most deadly and depressing of maladies If this virulent form were to reappear, those who fulminated against vaccination would rush to the vaccination officer for protection. Vaccination in connexion with small-pox was regarded wtih prejudice by a large number of people but of course, our vaccination laws were framed a good many years ago, and knowledge had increased and widened since then At present there were 70 different diseases, to secure immunity against which vaccination was practised Small-pox was the only disease in regard to which compulsory vaccination was applied It might be that the very fact that this particular disease was picked out and separated from the others for this exceptional legislative treatment had served to inflame the fanatical feelings against it which had led to so large a proportion of the population going without vaccination At any rate he had recently set up a Committee under the chairmanship of Sir H. D Rolleston, then President of the Royal College of Physicians to investigate the whole subject, and he was content for the present to await that report and any recommendation which they might make on the subject The only other disease which he would say a word about was sleepy sickness He thought a good deal of alarm had been created in this country by the very distressing after-effects of this disease There had been some very painful cases of after-effects showing the moral changes due to this particular complaint and it was unfortunately the case that as matters stood at present there was considerable difficulty in giving what they might regard as proper treatment to cases of this kind The legal definition of mental deficiency would not cover cases of persons who had been affected by *Encephalitis lethargica* There was something in certification for lunacy which was quite inappropriate for cases of this kind. That was a matter which was engaging his very serious attention, and it might be that he would have proposals to make to Parliament before very long to meet it In the meantime it might reassure hon Members to know that the disease appeared to be distinctly on the wane In 1924 the number of cases was 5039 In 1925 it came down to 2635, and therefore he thought they were justified in drawing the conclusion that this complaint which appeared so suddenly and developed so rapidly had reached its maximum and was now passing away; and that soon it would become, not a matter which could be neglected but one which would no longer give them serious concern and anxiety There were many other subjects which he had not touched upon If he had not said anything about the details of maternity and child welfare or venereal disease, or the much larger question of the future of the voluntary hospitals, it was not because he underrated their importance, but merely because he recognised that there must be some limit even to the patience and toleration of the Committee. He hoped however that he had said enough to show the huge extent of the field which was covered by his department and to point to the earnestness, and he thought also on the whole to the success with which they were grappling with the problems which confront them

Mr A GREENWOOD moved to reduce the vote by £100

Lieut -Colonel FREMANTLE said that the newspapers were full of statements with regard to the starvation of the children of the miners but he had seen no evidence in support of those assertions On the other hand, evidence from medical clinics and welfare centres went to show that the health of the children was better now than before the strike. Dealing with the question of deaths in childbirth Lieut -Colonel Fremantle said that in the interesting report on public health published for 1924, there were very serious figures showing how unprogressive had been the treatment of that question. Although there had been a considerable reduction in maternal mortality, it had not been anything in proportion to the reduction in infantile mortality Much more than that, there had been an actual increase in the mortality of women in childbirth. This showed that there was great room for an increase in the number of beds in maternity homes, especially in view of the lack of proper accommodation in working-class homes He was of opinion at the same time, that maternity homes should be regarded, not as permanent institutions, but as makeshifts until proper accommodation for maternity cases was provided in all homes In regard to town planning from the health point of view they saw really no earnestness on the part of local authorities to take the matter up Another question of great importance was the supply of clean milk. There was no provision for the supervision of health in coal-mines They heard of certain diseases among the men which were exceedingly troublesome The Ministry of Health ought to take up the attitude, more and more, of being responsible for the health of the people in every department, and of knowing what health conditions were all over the country

Dr VERNON DAVIES said that it was true that for the last 50 years there had been a very happy and steady decrease in the rate of tuberculosis, except in the war years 1913 to 1918 when, for temporary reasons, there was an increase But, despite that decrease, consumption was still our great white scourge, which took a terrible toll of the younger people Dealing with the machinery at the Ministry of Health for dealing with the disease, Dr Davies paid a tribute to the work of the panel practitioner who, he said, was the first link in the system of treatment The Ministry had added to the panel doctor the tuberculosis officers, who were expert in the diagnosis and treatment of consumption To get the full benefit of sanatorium treatment the cases must be taken early The great failure in the system of the Ministry of Health was the lack of village settlements and the Minister of Health ought to give a lead in that matter The Ministry should divide the cases of tuberculosis into two groups, those that could be cured and those which were too far advanced Sanatoria should be kept absolutely for the curable cases and the unfortunate people who could not be cured should be removed from their homes to the Poor-law hospitals His visit to Mr Spahlinger had convinced him that he had made out a *prima facie* case for his treatment The difficulty lay with Mr Spahlinger He was one of the most charming men and the very soul of honour He was a wonderfully clever scientist and was working on strictly scientific lines His whole object was the alleviation of distress among his fellow beings, and his determination if possible to stamp out the disease He was without the slightest desire for money But they found a difficulty in tying him down to any definite legal agreement. Now he had no money at all having spent £80 000 in his experiments for the good of humanity, and he was living from hand to mouth by taking odd patients who gave a subscription or donation to his institution. The one essential thing for Mr Spahlinger was to be able to produce his

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Bethlem Hospital Bill

THE Bethlem Hospital Bill, which has passed through the House of Lords, was read a third time

HOUSE OF LORDS

THURSDAY, JULY 8TH

University of London Bill

The House went into Committee on the University of London Bill, the Earl of DONOUGHMORE in the chair

Clause 7 (Provisions as to incorporation of colleges and schools in the University) provides as follows —

> (1) No statute made under this Act shall alter the incorporation in the University of the colleges known respectively as University of London, University College, and University of London, King's College, or the vesting, disposition, or management of any emoluments, endowments trusts, foundations, gifts offices, or institutions in or connected with either of those colleges so far as those matters are or have been regulated respectively by or under the University College, London (Transfer) Act 1905, or the King's College, London (Transfer) Act, 1908, and no such statute shall provide for the incorporation in the University of any school of the University or other college, school, or institution, but if at any time it is agreed between the University and the governing body of either of the first mentioned colleges that it is expedient that as respects that college any such alteration as aforesaid should be made, or if at any time it is agreed between the University and the governing body of any school of the University or other college, school or institution that it is expedient that provision should be made for the incorporation thereof in the University, then, in any such case, it shall be lawful for the University and the governing body jointly to make application to His Majesty in Council for a charter in that behalf, and any charter which His Majesty in Council is pleased to grant upon any such application shall have full effect notwithstanding anything in any Act of Parliament or in any previous charter, deed, or other instrument whatsoever

Earl BEAUCHAMP moved after Subsection (1) to insert the following new subsection —

> (2) Provided always that no Statute may be made under this Bill affecting any institution which was existing on Jan 1st, 1925, except with the consent of its governing body

He said that on the second reading the Earl of Balfour was good enough to say that he would consider this point, and the amendment had been put down with a view to carrying out his wishes The amendment would exclude existing colleges from the operation of the Bill He hoped that the Government would accept it

Lord ASKWITH supported the amendment The Bill was founded on the report of the Committee which dealt with the University as a whole and also in certain respects with the incorporated colleges and schools Clause 7 dealt with certain colleges of the University and said that statutes affecting them should not be altered at all That was perfectly reasonable If any statutes were to be altered it should only be by agreement with the particular colleges The clause provided that new colleges ought only be incorporated by agreement In Clause 4 there was a provision concerning existing colleges, but that clause was confined to cases where statutes were made not being statutes of the University There seemed, therefore, to be a gap

The Earl of BALFOUR, Lord President of the Council, said that the powers given to the University of making conditions with regard to these matters were distinctly excluded with regard to existing schools Where, then, was the danger against which the noble earl wished to guard? If it was really felt that with regard to the future of the colleges or with regard to any of the present colleges some safeguard in regard to religion was required His Majesty's Government had no objection to it The whole object of this Bill was to improve the position of the constituent bodies They did the teaching work of the University and it was their prosperity which was chiefly necessary if the internal side of the University was to carry out the functions which they all desired to see it exercise The notion that they were going to reform the University without in any way affecting the constituent colleges was evidently illusory In these circumstances he felt sure that the noble earl would not press his amendment in its present form

Viscount HALDANE said that he entirely agreed with what the Earl of Balfour had said The amendment would paralyse the work of the Commissioners and make it impossible for them to do a number of things for which they were looking It would be infinitely better to take the Bill as it stood, which restricted the powers of the Commissioners to the substance of the plan in the report and enabled them to survey the whole field and to deal with it in the only way in which it could be dealt with As to what outside colleges should come in that was a question only to be decided by the Commissioners after examining the evidence

The amendment was by leave withdrawn, and the Bill passed through Committee and was reported to the House

HOUSE OF COMMONS

THURSDAY, JULY 8TH

Progress of Housing in England and Wales

Mr HERBERT WILLIAMS asked the Minister of Health if he was now in a position to state the total number of houses completed in England and Wales in the 12 months ended March 31st, 1926 —Mr NEVILLE CHAMBERLAIN replied The total number of houses completed in England and Wales during the year ended March 31st, 1926, was 173,426—106,987 with State assistance and 66,439 without State assistance

Registration of Manipulative Practitioners

Colonel DAY asked the Minister of Health if would consider an inquiry into manipulative surgery with a view to the recognition and registration of manipulative practitioners —Mr NEVILLE CHAMBERLAIN replied No, Sir This question was fully discussed in the debate on Feb 9th on the motion of the hon Member for London University and I have nothing to add to the statement which I then made

Appointment of a Lay Member of the G M C

Mr ERSKINE asked the Vice-Chamberlain of the Household, as representing the Lord President of the Council what was the object in appointing a lay member on the General Medical Council —Major HENNESSY replied It would be contrary to practice to disclose the grounds upon which the Privy Council advised His Majesty to make the recent appointment No doubt my hon friend is acquainted with public discussion which has taken place in connexion with the constitution of the General Medical Council

Sir N GRATTAN DOYLE asked whether the appointment of a lay member signified any change of policy from that adopted by the General Medical Council in regard to Dr Axham —Major HENNESSY I cannot answer that question, but I do not think so

Mr ERSKINE Is the hon and gallant gentleman aware that Dr Cowie a registered practitioner, was now acting in the same capacity as Dr Axham had acted in times gone by to Mr (now Sir H) Barker

The SPEAKER said that seemed to involve individuals and might carry some implication which was not plain to him at the moment For that reason he would like to see the question in writing before it was put

Mr MACQUISTEN asked if it was not the case that the appointment of a lay member on the General Medical Council was to abate the autocracy of the medical profession and to dilute the fanatical trade unionism with which they were obsessed?

The SPEAKER said that the hon Member must try to abate some of his adjectives

MONDAY, JULY 12TH

Medical Inspection of Maternity Homes

Mr PENNY asked the Minister of Health whether, in view of the inability of nursing association committees to deal with the technical side of their activities, he would introduce legislation enforcing the composition of an advisory committee of local medical men in all cases in addition to the regulations for inspection now in force —Sir KINGSLEY WOOD replied It is clearly desirable that a nursing association which undertakes the management of an institution such as a maternity home should have the benefit of medical advice, but my right hon friend doubts whether it would be expedient to attempt to enforce, by legislation, such a condition as my hon friend suggests

Mr PENNY asked if the hon gentleman would consider any alternative way of doing this As these institutions were to a very large extent local institutions, would it not be better if local medical men inspected them periodically?

Sir K WOOD My right hon. friend, as the hon Member knows, has already made various suggestions with regard to this particular case, with a view to improvement, and if my hon friend has any suggestion to make I have no doubt that he will consider it.

External Degrees at London University

Mr HORE-BELISHA asked the President of the Board of Education whether the Government proposed to take steps by legislation to set up a statutory commission to give effect to the report of the Departmental Committee on London University, which would favour the abolishing of the external degrees of that University —Lord E PERCY replied The Government have introduced a Bill in another place to set up a Statutory Commission to give effect to the recommendations of the Departmental Committee But if the hon Member will look at paragraph 8 of the Committee's report he will see that it is explicitly stated that none of their recommendations is in any way designed to restrict the present facilities available for external students, or to prevent their development This statement corresponds with the views of the Government and it will be the duty of the Statutory Commission under the Bill to carry out the Committee s intentions in this matter

Infectious Illness among Members of the O T C

Mr **Rennie Smith** asked the Secretary of State for War if he could give an analysis of the infectious illness of 3660 members of the junior division of the Officers Training Corps who were for this reason prevented from attending camp in 1925 —Sir L. **Worthington-Evans** There are no records in possession of the department from which the desired information could be furnished as the boys in question did not attend camp I might add that it would be erroneous to assume that the 3660 members in question were ill The great majority were "contacts" who are not allowed to attend camp owing to the risk of spreading infection

Tuesday, July 13th

Progress of Public Health

The House went into Committee of Supply on the Ministry of Health vote, Mr J F **Hope** in the chair

On a vote of £18 117 048 for the salaries and expenses of the Department and other expenses in connexion with housing grants to local authorities for public health services, National Health Insurance administration &c

Mr **Neville Chamberlain** (Minister of Health) said that cancer was increasing at an alarming rate Last year in this country 1336 deaths from cancer occurred per 1 000,000, which was equivalent in our population to the death of 50,000 persons It had been estimated that out of every seven persons in this country who reached the age of 30 one would die of cancer It was important that the public should be educated so that the disease could be treated in its early stages The significance of the discovery of Dr Gye and Mr Barnard was that cancer was due to a virus which entered the body from outside, but which did not produce cancer until it was associated in the body with some other factor, the nature of which had not yet been clearly ascertained The right hon gentleman directed the attention of local authorities to the experiment which was being carried out at Papworth, near Cambridge, by Dr Varrier-Jones in regard to the after treatment of tuberculosis Here, he said, was a chance for one of our big progressive local authorities to start a settlement of its own on Papworth lines Dealing with small-pox Mr Chamberlain stated that the disease was rapidly increasing in this country The number of cases were as follows :—In 1922 973, 1923 2500 1924, 3800 1925, 5300 and in the first six months of this year, 5500 cases This increase could not be regarded without a great deal of anxiety It was true that at the present time the disease was present in a very mild form, but in the past they had had this mild form coexisting with a form which was one of the most deadly and depressing of maladies If this virulent form were to reappear, those who fulminated against vaccination would rush to the vaccination officer for protection. Vaccination in connexion with small-pox was regarded wtih prejudice by a large number of people but of course, our vaccination laws were framed a good many years ago, and knowledge had increased and widened since then. At present there were 70 different diseases, to secure immunity against which vaccination was practised Small-pox was the only disease in regard to which compulsory vaccination was applied It might be that the very fact that this particular disease was picked out and separated from the others for this exceptional legislative treatment had served to inflame the fanatical feelings against it which had led to so large a proportion of the population going without vaccination At any rate he had recently set up a Committee under the chairmanship of Sir H D Rolleston, then President of the Royal College of Physicians to investigate the whole subject and he was content for the present to await that report and any recommendation which they might make on the subject The only other disease which he would say a word about was sleepy sickness He thought a good deal of alarm had been created in this country by the very distressing after-effects of this disease There had been some very painful cases of after-effects showing the moral changes due to this particular complaint and it was unfortunately the case that as matters stood at present there was considerable difficulty in giving what they might regard as proper treatment to cases of this kind The legal definition of mental deficiency would not cover cases of persons who had been affected by *Encephalitis lethargica* There was something in certification for lunacy which was quite inappropriate for cases of this kind That was a matter which was engaging his very serious attention, and it might be that he would have proposals to make to Parliament before very long to meet it In the meantime it might reassure hon Members to know that the disease appeared to be distinctly on the wane In 1924 the number of cases was 5039 In 1925 it came down to 2635, and therefore he thought they were justified in drawing the conclusion that this complaint which appeared so suddenly and developed so rapidly had reached its maximum and was now passing away, and that soon it would become, not a matter which could be neglected but one which would no longer give them serious concern and anxiety There were many other subjects which he had not touched upon If he had not said anything about the details of maternity and child welfare or venereal disease or the much larger question of the future of the voluntary hospitals, it was not because he underrated their importance, but merely because he recognised that there must be some limit even to the patience and toleration of the Committee He hoped, however that he had said enough to show the huge extent of the field which was covered by his department and to point to the earnestness, and he thought also on the whole to the success with which they were grappling with the problems which confront them

Mr **A. Greenwood** moved to reduce the vote by £100

Lieut -Colonel **Fremantle** said that the newspapers were full of statements with regard to the starvation of the children of the miners but he had seen no evidence in support of those assertions On the other hand evidence from medical clinics and welfare centres went to show that the health of the children was better now than before the strike Dealing with the question of deaths in childbirth Lieut -Colonel Fremantle said that in the interesting report on public health published for 1924 there were very serious figures showing how unprogressive had been the treatment of that question Although there had been a considerable reduction in maternal mortality, it had not been anything in proportion to the reduction in infantile mortality. Much more than that there had been an actual increase in the mortality of women in childbirth. This showed that there was great room for an increase in the number of beds in maternity homes, especially in view of the lack of proper accommodation in working-class homes He was of opinion at the same time, that maternity homes should be regarded, not as permanent institutions, but as makeshifts until proper accommodation for maternity cases was provided in all homes In regard to town planning from the health point of view they saw really no earnestness on the part of local authorities to take the matter up Another question of great importance was the supply of clean milk. There was no provision for the supervision of health in coal-mines They heard of certain diseases among the men which were exceedingly troublesome. The Ministry of Health ought to take up the attitude, more and more, of being responsible for the health of the people in every department, and of knowing what health conditions were all over the country

Dr **Vernon Davies** said that it was true that for the last 50 years there had been a very happy and steady decrease in the rate of tuberculosis, except in the war years 1913 to 1918, when for temporary reasons, there was an increase But, despite that decrease, consumption was still our great white scourge which took a terrible toll of the younger people Dealing with the machinery at the Ministry of Health for dealing with the disease, Dr Davies paid a tribute to the work of the panel practitioner who, he said, was the first link in the system of treatment. The Ministry had added to the panel doctor the tuberculosis officers, who were expert in the diagnosis and treatment of consumption To get the full benefit of sanatorium treatment the cases must be taken early The great failure in the system of the Ministry of Health was the lack of village settlements and the Minister of Health ought to give a lead in that matter The Ministry should divide the cases of tuberculosis into two groups, those that could be cured and those which were too far advanced Sanatoria should be kept absolutely for the curable cases and the unfortunate people who could not be cured should be removed from their homes to the Poor-law hospitals His visit to Mr Spahlinger had convinced him that he had made out a *prima facie* case for his treatment The difficulty lay with Mr Spahlinger He was one of the most charming men and the very soul of honour He was a wonderfully clever scientist and was working on strictly scientific lines His whole object was the alleviation of distress among his fellow beings, and his determination if possible to stamp out the disease He was without the slightest desire for money But they found a difficulty in tying him down to any definite legal agreement Now he had no money at all, having spent £80 000 in his experiments for the good of humanity, and he was living from hand to mouth by taking odd patients who gave a subscription or donation to his institution. The one essential thing for Mr Spahlinger was to be able to produce his serum and enlarge his laboratory and stock He (Dr Davies) appealed to the Minister of Health to vote a certain sum, say, £50,000 or £100,000, to Mr Spahlinger for the purposes of his research work

Dr Watts said that the vaccination laws were administered in too lax a manner Only a small proportion of infants were vaccinated This was due more to the carelessness of parents than to conscientious objection to vaccination Yet there were very few prosecutions for breaches of the law The increase in the number of cases of small-pox was due to this laxity, and it also explained the action taken by foreign countries, such as the United States, to see that British sailors were vaccinated before they were allowed to land

Dr Haden Guest said that he thought that Mr Spahlinger's work might be of value, but it was an occasion for private rather than public enterprise He hoped that something might be done in that way He thought he was speaking for medical opinion as a whole when he said that the real way of dealing with tuberculosis was by preventive rather than curative methods If, for instance, they could make such an improvement in the standard of life of the people in this country that everybody every day in the year would have an adequate amount of food and would not do an excessive amount of work, the consumption statistics would fade almost out of existence He thought that experiments which had been undertaken in providing workshops for men who had been discharged from sanatoria, where they could learn to take up life again under normal conditions, were on the right lines, and would be of great assistance to such men

Sir M Macnaghten referred to a letter issued by the Ministry of Health to the Edmonton District Council, which, he said, placed an absolute prohibition on a doctor in a maternity centre giving advice or information to a woman on the subject of birth control The letter stated that while a doctor could not give the advice himself, he might refer the woman for advice to a private practitioner or to a hospital If the instruction was not complied with, the grant would be withdrawn. Obviously, he said, maternity centres ought not to be converted into birth control clinics, but all that was asked was that in the case of a poor woman a doctor should be in a position to give this advice and information without incurring the penalty attached to the instructions of the Ministry

Dr Shiels said he associated himself with other speakers in appreciation of the results of the Spahlinger treatment, but there were considerable difficulties to be faced He thought that the Minister should keep his mind open in regard to the possibility of acquiring this treatment for those who suffered from tuberculosis He was glad that the Ministry would encourage local authorities to show initiative in the establishment of village settlements Sunlight and artificial sunlight treatment had a great effect on certain types of tuberculosis, especially surgical tuberculosis There had been some misunderstanding of the position of the Ministry in the matter, because many local authorities had the impression that the Ministry did not encourage the setting up of installations for this treatment He hoped the misunderstanding would be cleared up, because the treatment was long past the experimental stage It was also of great value in the treatment of rickets in children The milk-supply of this country was by no means what it should be, and was far behind that of the United States The Ministry should continue its efforts to try to eliminate tuberculous milk altogether This country consumed, per head of the population, far too little milk, but they could not really urge mothers to give their children more milk unless they were sure that it was safe More broad-mindedness should be shown, also, in the allocation of financial assistance for cancer research

Sir Kingsley Wood, replying to the debate, said that undoubtedly the corner had been turned so far as housing was concerned, and at last they were beginning to catch up the shortage He could give an assurance that whatever decision was reached in regard to the housing subsidy in October, no alteration would be made in the financial contributions for the removal of slums Thanks to the Economy Bill, the Minister had now been able to give the following increases and additional benefits to all men belonging to the Army and Navy They would have an extra sickness benefit over and above the ordinary amount received of 3*s* a week, making the total up to 18*s* The disablement benefit would be increased by 1*s* 6*d* a week making a total of 9*s* a week The maternity benefit would be increased by 6*s*, making the maternity benefit to people in the Army, Navy, and Air Force Insurance Fund up to no less than 46*s* They would also receive extra benefits in the way of dental and ophthalmic treatment In regard to the Spahlinger treatment, offers had been made to Mr Spahlinger, and it was no fault of the various Ministers of Health that no further trial had been made in this matter It was utterly impossible for the Minister of Health to make a gamble of £100,000 in the present circumstances In regard to the question of medical men being allowed to give advice on birth control at maternity centres before the Minister could make an alteration in public policy on that matter, there must be a much greater measure of public opinion behind it

The amendment to reduce the vote was rejected by 255 votes to 107, and the debate was adjourned

Doctors on British Cargo Ships

Mr Ponsonby asked the President of the Board of Trade with what number of crew and passengers British cargo ships were allowed to sail without having any doctor on board whether this number was fixed by departmental regulation, and was he satisfied that no hardship was involved by the absence of a doctor on ships not carrying the requisite number, more especially in cases where the ship was not fitted with wireless apparatus —Sir P Cunliffe-Lister replied Section 209 of the Merchant Shipping Act, 1894, requires a doctor to be carried on every foreign-going ship having 100 persons or upwards on board I think in all the circumstances the rule is a reasonable one The hon Member will appreciate that it would be impracticable to compel ships of a size so small as to be exempt from carrying a wireless apparatus to maintain a doctor

Payment of Sickness Benefit in Scotland

Mr Johnston asked the Under-Secretary to the Scottish Board of Health whether he was aware of the delays which took place in Scotland in the payment of sickness benefit to persons insured under the National Health Insurance Act, and whether he would take steps to prevent health insurance societies delaying payments of sickness benefit while corrections of a trivial and technical nature were being made on the claim form or the proposal form where these conflicted —Major Elliot replied I am not aware that any considerable delay takes place in Scotland in the payment of sickness benefit to insured persons This question was recently considered by the Royal Commission on National Health Insurance, to whom evidence was submitted by the Scottish Board of Health on an analysis of 8000 cases Of this number it was found that more than 83 per cent of the insured persons involved received payment within four days to a week of the dates of the claims, about 14 per cent received payment within 14 days, and that therefore only a very small residue of cases were delayed longer than a fortnight, sometimes on account of causes for which the insured persons were themselves responsible I do not think therefore that any action on my part is called for such as is suggested in the second part of the question, but if any case where avoidable delay has taken place is brought to my notice I shall make inquiries

Pure Milk Regulations

Colonel Day asked the Minister of Health when the pure milk regulations were likely to be brought into effect —Sir Kingsley Wood replied The Milk and Dairies Order, 1926, will come into operation on Oct 1st next The Public Health (Imported Milk) Regulations, 1926, will come into operation on Jan 1st, 1927

Brigadier-General Clifton Brown asked the Minister of Health what steps were taken to ensure that foreign condensed skimmed milk and other milk products imported from abroad were free from deleterious matter and whether, in view of the proposed milk and dairy orders enforcing milk producers in this country to provide clean milk, he would prevent distributors in this country mixing British milk with any imported substance —Sir Kingsley Wood replied The Public Health (Imported Milk) Regulations, 1926, impose a standard for the bacterial content of imported milk and require it to be free from tubercle bacilli I am sending my hon, and gallant friend a copy of those Regulations and also of the Public Health (Imported Food) Regulations, 1925 I may further refer him to the provisions of Section 1 of the Sale of Food and Drugs Act 1899, which deals with the importation of adulteration or impoverished milk or cream The addition of any dried or condensed milk or any fluid reconstructed therefrom or any skimmed milk or separated milk to milk intended for sale is prohibited by Section 4 of the Milk and Dairies (Amendment) Act, 1922

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole street, W

MONDAY, July 19th, to SATURDAY, July 24th.—Special afternoon demonstration in Clinical Ophthalmology at the Royal Eye Hospital, St George s Circus S E., on July 19th, at 3 P M by Mr Letchworth. Open to all members of the medical profession without fee —PRINCE OF WALES S GENERAL HOSPITAL, Tottenham, N; Intensive Course in Medicine, Surgery, and the Specialties Daily, 10 30 A.M. to 5 30 P.M. Clinical and laboratory methods, demonstrations, operations general hospital clinics and clinical lectures —WEST END HOSPITAL FOR NERVOUS DISEASES Welbeck-street, W. A series of lectures, including clinical demonstrations on selected cases, on the diagnosis and treatment of common diseases of the nervous system. Daily, 5 P.M. Monday to Friday inclusive —ROYAL EYE HOSPITAL, St George s Circus Southwark, S E. A series of demonstrations on the diagnosis and treatment of diseases of the eye. Daily at 3 P.M. Further information from the Secretary of the Fellowship

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales s General Hospital, Tottenham, N.

MONDAY, July 19th, to SATURDAY, July 31st.—Special Vacation Course First week daily to Friday 10 30 A.M. to 12 45 P.M. Demonstrations of clinical and "side-room" methods 2 P.M. to 2 45 P.M., Demonstrations of Groups of Clinical Cases. 2 30 P.M. onwards General Hospital Work, Clinics &c 4.30 P.M., Clinical Lectures. Monday, Dr T Watts Eden Antenatal Care as it Affects the Child in utero Tuesday, Dr F G Crookshank Influenza. Wednesday, Mr. E Gillespie Colitis from the Surgical Aspect Thursday Mr. J Howell Evans Intestinal Diverticula and Diverticulitis Friday Dr C E. Sundell. Abdominal Tuberculosis in Children.

SATURDAY.—11 A.M. Dr F Thomson: Demonstration of Cases illustrating the Early Diagnosis and Treatment of the Infectious Fevers (at the North-Eastern Fever Hospital St Ann s road N)

LONDON SCHOOL OF DERMATOLOGY, St John s Hospital, Leicester-square W C

TUESDAY July 20th.—5 P.M., Dr H. W. Barber Scleroderma.

THURSDAY July 22nd.—5 P.M., Dr J H. Sequeira. Skin Affections of Animals Transmissible to Man.

Appointments.

HORSFORD CYRIL, M D Edin., F R.C.S has been appointed Hon. Laryngologist to the Royal College of Music.

PARKER, W M.B, Ch.B Edin. D P.H., County Medical Officer Worcestershire

PLATT H, M.D Manch., M.S Lond. F R.C.S Eng Honorary Clinical Lecturer in Orthopædics in the University of Manchester

WILLIAMS ANNA M. M.B Edin., D.P H, Assistant Medical Officer, Birkenhead.

WOODMAN MUSGRAVE, M.S Lond., F.R.C S Eng Lecturer, Diseases of the Nose and Throat University of Birmingham.

Sheffield Royal Hospital HOLMES, E. M.B, M R.C S, Resident Surgical Officer FRIZELLA, E., M.B M.Ch. Casualty Officer FLINT R. L M B B Ch. JAGO, J W M.B, Ch.B House Surgeons BEATTIE, W. M.B, Ch B, SYKES E. M B Ch.B House Physicians: JAGO, J. L. M B, Ch.B, Aural House Surgeon BLAKELOCK, J H M B., Ch B Ophthalmic House Surgeon FAIRCLOUGH J H M.B Ch B CALLCUTT J S M.B Ch.B. Casualty Officers TOWNROW, V. M.B, B S Lond., Assistant Supernumerary Surgeon to Ear, Nose and Throat Department, YATES, H B M.B, Ch.B Camb, F R.C S. Eng, Assistant Honorary Surgeon: CHISHOLM, J, M.B, Ch.B. Edin., Honorary Consulting Gynæcological Surgeon.

University of Sheffield GUEST, DENTON M B, Ch.B Sheff, combined post of Demonstrator in Pathology and Assistant Pathologist to the Royal Infirmary

Vacancies.

For further information refer to the advertisement columns

Bangor Carnarvonshire and Anglesey Infirmary —H S £200

Bolingbroke Hospital, Wandsworth Common.—Asst. Hon. Phys

Bury Infirmary —Radiologist £150.

Cambridge, Addenbrooke's Hospital —Cas Officer. £130.

Cardiff City Council —Pupil Asst M.O. £300

City of London Hospital for Diseases of the Heart, &c.—Two H Phys £100 each

Darlington County Borough —M.O.H £900

Derbyshire County Council —Asst County M.O £750.

East African Medical Service.—Sanitation Officer £660

Evelina Hospital for Children South-wark.—House Surg At rate of £120 Also Hon. Dental Surg

Grosvenor Hospital for Women, Vincent-square, S W.—Hon. Asst. Gynæcologist

Halifax Royal Infirmary —First H S £250

Hospital for Consumption and Diseases of the Chest, Brompton, S W —Pathologist £750.

Inverness The Northern Infirmary —Sen. H S £120

Liverpool County Borough —Junior Asst School M.O £600.

Liverpool, Royal Liverpool Children's Hospital —Two R.H.P. and two R.H.S At rate of £60 each p a. R.M.O. £150.

London Skin Hospital —Hon. Phys

Manchester Ear Hospital —H S £150

Manchester, St Mary s Hospitals —Two H.S 's Each at rate of £50

Metropolitan Hospital, Kingsland-road —Hon. Anæsthetist and Ophth Surg

Miller General Hospital, Greenwich-road —S.R.M.O £250

Nottingham Education Committee.—Asst. School M.O £600

Rotherham Hospital —Jun. H S. £150

St Helen's County Borough —Asst M.O £600 Also Asst. M.O H (Tuberculosis) £450.

St John s Hospital for Diseases of the Skin, 49, Leicester-square W C —Pathologist £100

St Paul s Hospital for Skin Diseases —Res. M.O £250.

Seychelles Government —Asst M.O R 6500 per annum.

Staffordshire County Council —Bacteriologist £10 10s per week.

West End Hospital for Nervous Diseases —Hon. Phys and Hon. Surg

West London Hospital, Hammersmith-road, W.—Res Asst S. £200

Wolverhampton and Staffordshire Hospital.—H.S At rate of £150

Wrexham and East Denbighshire War Memorial Hospital —S and J H Surgeons £120 and £80 respectively

York, County Hospital —H S. £150

The Chief Inspector of Factories, Home Office, Whitehall, S W, announces a vacancy for a Certifying Factory Surgeon at Weston-super Mare (Somerset)

Births, Marriages, and Deaths.

BIRTHS

ANDREWS —On July 9th at a nursing home Faversham Kent, the wife of R. Collingwood Andrews, L.D S R.C S Eng, of a son.

GODSON —On July 9th, at Welbeck-street the wife of Lieut.-Colonel C A. Godson, M.C, I.M.S., of a son.

MILLER.—On July 6th, at Emperor s-gate, S W, the wife of Dr Wm. Duff Miller, of a daughter

SCOTT —On July 7th at Fellows-road Hampstead, N W the wife of Edward Spencer Scott, M.D., of a son.

MARRIAGES

FARR—CAPPER.—On July 10th, at Holy Trinity Church Brompton, Valentine Francis, M.B, B Sc Lond., to Margery Bayliss, younger daughter of Mr and Mrs. H. W. Capper, of Harvard-road, Gunnersbury.

WISHART—BEDALE.—On July 7th at St Thomas s Church, Coventry, George Macfeat Wishart, M.D, to Elizabeth Mary, second daughter of the late Canon Bedale.

DEATHS

CADGE.—On July 9th, at Helmingham House, Kirkley Cliff-road Lowestoft William Hotson Cadge Lieut.-Colonel, I.M.S (retd.), in his 73rd year.

HANSON —On July 6th the result of an accident Dr Helen Beatrice de Lastricke Hanson, Assistant Medical Officer, L.C C

PARKER.—On July 10th at the Fanings, Lewes G F. Parker, M.R.C.S and L.S.A. aged 89.

SHERBURN —On July 7th at Brantinghamthorpe, Brough East Yorks John Sherburn, M B, C.M. Edin., J P, in his 75th year

WEEKES —On July 3rd at Modbury South Devon, Reginald Newton Weekes L.R.C P, M.R.C.S

N.B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE PREVENTION OF INSANITY *

A PRELIMINARY SURVEY OF THE PROBLEM

By Prof George M Robertson, F R C P Edin

Prophylaxis

Prophylaxis may be defined simply as the prevention of an attack of insanity when it threatens but before definite symptoms have appeared It goes further than this however as it includes the taking of measures to avoid conditions which would favour an attack, for hygiene of the mind and of the body is prophylaxis in a general way The term is applied here to particular steps taken with the immediate object of protecting the mind when threatened by danger There are certain persons for whom prophylaxis is almost essential—for example, those with a known hereditary predisposition who have already suffered from an attack, and more especially those in whom the attack has been of a recurrent type, such as manic-depressive insanity When such a case occurs the family physician should also bear in mind that the other members of the family inherit a similar predisposition

Danger Signals

Loss of sleep is first among the indications or warnings that should be attended to The neuropath is usually a bad sleeper, so that every time he loses a night's sleep, it must not be assumed that an attack of insanity is impending But extreme or prolonged insomnia is a danger and precautions should then be taken Sleep should be sought for in natural ways and encouraged by avoiding everything that might prevent it, but a time comes when hypnotics administered with knowledge and under strict medical supervision are of the very greatest value The public hear much of drug addiction or mania, the general physician is familiar with the craving for "tonics" and other medicines, but only the psychiatric physician comes in contact with the layman's horror of hypnotic drugs, which, despite its manifest advantages interferes occasionally with prophylaxis

Prolonged anxiety that cannot be dislodged runs insomnia close as a danger signal The evils that follow in its train are many and at the climacteric and presenile periods of life they may culminate in a mental breakdown The causes of the anxiety may be real and it may be very difficult to ease the tension before matters grow worse The victims of the strain of anxiety may complain of restlessness, of irritability, of being unable to settle down to work, of having difficulty in fixing attention, and of insomnia

Another danger signal is *mental and physical exhaustion* While rest alone will benefit those cases which are simply due to overwork and want of sleep, in other cases unless the primary cause be discovered and removed the improvement will be only temporary The functions of the nervous system may be lowered in tone and a state of neurasthenic fatigue produced by prolonged poisoning from a septic focus Mental depression is also accompanied by a failure of energy both mental and physical and a neurasthenic state may be associated with anxiety

A *change of character* not amounting to actual insanity, is another important sign, particularly in those who are subject to manic-depressive insanity In this form of insanity there are periodic phases of variable duration in which the patient is morbidly elated and others in which he is morbidly depressed Many people, including some of the most able and brilliant, are subject to similar moods, not amounting to insanity, these are said to suffer from cyclothymia or to possess the cyclic temperament These changes of mood can be controlled only to a limited extent, but much can be done to prevent their exaggeration into something definitely morbid The measures employed in such prophylaxis are of the simplest kind change of surroundings, relaxation, new interests, life in the open air, rest sleep, moderation in all things, and attention to the bodily health

The one important rule for the predisposed is not to ignore danger signals or warnings A sign may seem simple, even trivial, yet it may mean much

Early Treatment

It is a common-place that the earlier treatment is begun, the more hopeful are its results, but early treatment implies a recognition of the early symptoms of disease There is still much difference of opinion as to the early symptoms of insanity It is believed by many that some of the cases receiving treatment for the prevention of insanity would not develop insanity were they to receive none They believe that these cases of the psychoneuroses which others regard as exhibiting the early stage of insanity, suffer really from a definite mental disorder of a different kind It is even alleged that the presence of a psychoneurosis is a protection against insanity This is a point of some importance since if it is true, neurologists and others who have had little experience of true, insanity may perhaps be over-valuing the services they render At the International Congress of Mental Medicine held in Paris in 1889, when this question was considered (*Comptes Rendus*, p 36) it was agreed that psychasthenia, consisting of obsessions accompanied by anxiety, hesitancy in thought and action and physical phenomena, preserves the same psychic character throughout the whole life of affected individuals and does not change into other forms of mental disease In rare instances it may be complicated with delusions of persecution, with anxious melancholia, and with hallucinations I am inclined to agree that once a psychoneurosis has assumed a definite form, although it varies from time to time in its severity and in the details of its symptomatology, it does not tend to alter its character or to assume that of insanity, any more than one definite form of fully developed insanity tends to alter into another To this extent the treatment of the psychoneuroses is not the early treatment of insanity, nor can such treatment claim to prevent insanity from developing where that danger does not exist To this extent also the existence of a definite type of psychoneurosis, except in rare instances, may be said to protect the individual from the occurrence of actual insanity He must, however, qualify this opinion by the observation, that at an early stage it is impossible to foretell whether transient, vague, and disorderly mental phenomena will develop into a typical psychoneurosis or into a definite form of insanity There are thus two stages, an initial stage when anything is possible, and a later stage when the type is fixed

Prevention of the Acquired Insanities

In the middle period of life when the acquired insanities are prevalent the benefits of prevention are more noticeable because they are more immediate Alcoholic insanity and general paralysis occur at this period, and there are many other forms, for example, the confusional insanities, called from their causation the infective-exhaustive-toxic insanities Although in these, as in all forms of insanity, hereditary predisposition plays its part, they are largely acquired and can often be prevented Nothing need be said about these forms of insanity excepting that due to myxœdema, which has diminished almost to vanishing point since the discovery of its cause was made Just as heredity is a factor to be reckoned with to a greater or lesser extent, in every case of insanity, so we are beginning to recognise that disturbance of the internal secretions plays a more or less important part in all forms of mental disorder If the future holds for us a great therapeutic discovery in the domain of mental disease, it will probably be found in a knowledge and control of the internal secretions

Alcoholism and Temperance

As regards the prevention or abolition of alcoholic insanity, there is a very simple way of effecting this, provided it is voluntary But even if alcohol were prohibited not in the legal but in the real sense, the total number of cases of insanity would not be diminished by the full number of cases diagnosed as alcoholic insanity Many of these, owing to inherent instability, would break down from other causes in the absence of alcohol On the other hand alcohol is a contributing factor but not the principal cause of insanity in many other cases, and in these abstinence might be the means of averting insanity altogether Alcoholic insanity is diminishing, though not so rapidly as most people desire

G P I —Education and Salvarsan

Another important form of acquired insanity is general paralysis of the insane There are two promising remedies, for its treatment benign tertian malaria and tryparsamide, after it has actually appeared An astounding fall in the number of deaths was recorded in 1919, the fact that this fall has continued is of supreme interest from the point of view of prevention From 1907 to 1918 inclusive the number of male deaths was steady, and for eight years the biennial numbers did not vary more than ten In 1919–20 there was a sudden drop of 26 per cent The probable explanation of this sudden fall in the number of deaths is as follows General paralysis may appear within three years after syphilis has been contracted, but it is not till seven years have elapsed that it occurs with any frequency Of those attacked more than a half die within two years after the first appearance of the symptoms, which are usually present for a year before the patient is admitted to a mental hospital If, therefore, persons develop general paralysis seven years r infection, and if half die within two years, we require o back nine years to find an explanation for any variation the death-rate. In other words to explain a sudden in the number of deaths in 1919 we require to investigate ditions in 1910. If this be done an explanation is found the employment during that year of salvarsan and the re by its use of those males who contracted syphilis the fall in the number of deaths in 1919–20 is 26 per cent., is certain that many who had contracted syphilis previous 1910 and 1911 also took advantage of the discovery the new remedy. As to females there was a steady ll from 1907 to 1918, doubtless due to the gradual education males as to the danger of passing on an infection.

---

* An abstract of the concluding part of the Maudsley lecture, of the Royal Medico Psychological Association, delivered on July 15th, 1926

There was a further fall of 33 per cent. in the number of male deaths from general paralysis in 1919–20 as compared th the two previous years. This corresponds exactly th the fall in the deaths of males in time and proportion ut it was not directly due to treatment by salvarsan as as the case with males. It may, however, be traced to the mployment of a rapid method of curing syphilis with the esult that the infectious stage of the disease in males was ut short by salvarsan and fewer women became infected.

These observations teach us two lessons. The first the success of modern scientific methods in preventing this terrible sequela of syphilis, and the second, the effect of educational propaganda. I attribute the whole fall in the number of deaths from general paralysis among females up to the year 1919 to the instruction given to infected males. It must not be concluded that as striking results will follow the appeal to women as have followed the appeal to men. The majority being innocently infected do not at present spread infection. There is, however, a virulent minority of immoral women to whom an appeal would be made in vain. Such women can be induced to come for treatment only in their own interest, and they are coming.

Prevention of Senile Insanity

As to measures for the prevention of insanity during senility we are guided by the knowledge that the later in life insanity begins the less important is the factor of hereditary predisposition in its causation, and that in all forms of insanity occurring during senility the influence of the body, if not paramount, predominates. The margin of bodily resistance to mental breakdown is less in old age than at any other period of life, but senescence is a period of retirement, of a withdrawal from the fierce zone of life's battle. There is then not only decreased alertness of mind and diminished vigour but a lowering of the sensibility which softens the effects of the harsh blows of fate. Sickness benefit, old age pensions, improved housing, better sanitation, and a higher standard of living may also be expected to have a direct effect in reducing the amount of insanity during this period of life. Without doubt preparation for a healthy old age by careful living during the middle period of life is the best insurance against senile insanity. In spite of this, however, hereditary tendencies to special diseases, such as vascular degeneration, may produce mental collapse as well as shorten life.

Is Insanity on the Increase?

All nations seem to pass through periodic phases in which fears arise that among them the occurrence of insanity is on the increase. So far as can be judged, the outlook in Scotland at the present time is distinctly favourable. Taking the last 15 years, the total number of insane persons has fallen from 390 per 100 000 in the first quinquennium to 369 in the last, and the number of insane persons registered annually for the first time has fallen from 2828 in the first quinquennium to 2731 in the last, although the population has increased in number. In these statistics there is no cause whatever for alarm.

Conclusion

It must be apparent to everyone that the problem of preventing mental disorder is not a simple one. The possible causes of mental derangement are legion, and the possible combination of these in individual cases beyond counting. It is clear that when sickness of mind threatens or occurs mental health cannot be regained by any royal road.

In the opening up of preventive channels a great responsibility rests on practising psychiatrists. It is futile to lament that those of unstable equilibrium turn elsewhere for help—to the quack, to the charlatan, to the barren ritual of the latest cult. The blame for this state of affairs must be shared by the psychiatrist. Far too long has he sulked in his cave; now he must come out into the market-place and offer his wares to all who need them. He must not confine his interests to his duties in the mental hospital. He must coöperate with the general practitioner and get into touch with the outer world through the agency of out-patient clinics.

An expert body of psychiatrists trained in every device of medicine and psychology and diligently applying themselves to the clamant needs of their generation might avert much needless suffering on the part of those in mental difficulties or about to be overwhelmed. Let none be daunted by the magnitude of the enterprise that is envisaged, but rather find in it an incentive to continued and combined effort.

WOMEN'S ORGANISATIONS IN RELATION TO SOCIAL HYGIENE

In The Lancet of June 26th we gave a general account of the annual general meeting of the British Social Hygiene Council held at 1, Wimpole-street, London, W., Mr. E. B. Turner presiding. The annual report and accounts having been adopted, officers and members of the Executive Committee for the ensuing year were elected. The new President is Lord Willingdon, formerly a Vice-President; the other Vice-Presidents and the principal officers remain unchanged. Dr. Valeria Parker, Director of the Department of Protective Measures, American Social Hygiene Association, and President, National Council of Women, United States of America, gave an address on the

Relation of Women's Organisations to the Social Hygiene Programme in the United States

She recalled the origin of a social hygiene programme in the United States when the National Women's Christian Temperance Union was organised in the early seventies. The Purity Committee of this union, later known as the Social Morality Committee, was concerned with the breaking down of the system of prostitution that had grown up in some of the larger cities and was determined to promote a high and equal standard of morals for both sexes. Social hygiene committees had since been formed in connexion with the National League of Women Voters, with the National Congress of Parents and Teachers and with the General Federation of Women's Clubs. The National Women's Medical Association had formed a committee for race betterment, and that a special committee, of which the speaker was chairman, was making a study of the number of clinics and number of antenatal clinics which are undertaking the proper diagnosis and treatment of venereal diseases for expectant mothers; Dr. Parker was therefore particularly interested in the report of the work in this direction carried out in Great Britain. She said that in the United States a grant was made from the Government, through the Children's Bureau, for the protection of maternity and infancy, and it was desired to know accurately to what extent such clinics are including the diagnosis and treatment of venereal disease. It was felt that the mother and the child should be given the benefit of such scientific discoveries as have been made for their protection.

The women's organisations in the United States had a very strong influence; they formed not only a channel through which education can be brought to the public in general, but are also a very powerful means of changing public opinion and of bringing about action.

In 1918 funds were provided by the American Government for education, research, and legal measures, and the reduction of venereal disease by means of public clinics, but to enable them to avail themselves of a proportionate amount of this money each State was required to agree to classify venereal disease as contagious. Each of the 48 States complied, Nevada being the last in 1922. The central funds were no longer available, but each State now financed its own work. The women's organisations had made no public protest against the classification of the venereal diseases, but they were opposed to the tendency to regard all women leading the lives of prostitutes as carriers of disease, this tendency having been carried in some cities to the extreme of subjecting all prostitutes arrested to an examination for venereal disease before conviction; those found free were released at once, and those found infected were detained. This procedure was being overcome by education as to the danger of male disease carriers and a persistent demand for equal administration of the law. Dr. Parker considered that the feeling of the majority in her country was that the fact that the law had been misused was not evidence that the law should be repealed, but that a strong effort should be made to secure the equal administration of the law for both men and women.

After the war a peace-time programme was formulated of which the educational side was still considered one of the most important factors. As a result of the change in public opinion, only one city—Reno, Nevada—remained where a segregated district is permitted.

In conclusion Dr. Parker emphasised the desirability of enlisting the support of all women by interesting them in the subject, and expressed her opinion that the appointment of women police in communities was a most important step that should be taken. She urged the British Social Hygiene Council to consider how best to use women's organisations as one of the means of carrying forward the excellent programme that she had heard outlined.

MALARIA IN ITALY

One of the landmarks in the progress of medicine is the mastery gained over malaria, which has been responsible for such countless deaths since the beginning of historic record As Baron Bernardo Quaranta di San Severino said in a lecture illustrated by a cinematograph film at the Royal Army Medical College on July 12th under the auspices of the London School of Hygiene and Tropical Medicine, the fixed idea of "bad air," "mala-aria," created an irresistible legend which forced people to run away from malarial zones with the consequent neglect and abandonment of those areas, thus making local conditions worse He pointed out that the Etruscans in earliest times mastered the art of building canals for draining, while later in the Roman epoch, when the conditions of the city during the first rulers were the cause of marsh fever, the Tarquins built a marvellous drainage system which is even in use at the present day As, however, the danger of malaria never disappeared there were inaugurated the worship of the goddess of fever, and of Castor and Pollux, the gods of health, of Lucifer, of Æsculapius, and of Apollo, whose statues were discovered near the Fons Juturna famous for the healing power of its waters The disease then was attributed to bad water as well as bad air and many ideas were conceived as a means of purifying malaria-infected spots In quite recent times trees and plants exhaling peculiar resinous perfumes have been cultivated with this object, such as eucalyptus, cypress, pines, and sunflowers but the cause of the spread of malaria evaded all theories until recently It is interesting therefore, to learn that from the most remote times certain African tribes protected themselves from malaria with a kind of mosquito net The lecturer alluded to the well-known writings of Giovanni Maria Lancisi, a celebrated physician of the seventeenth century, as containing a clear allusion to the mosquito as a malaria carrier and showed that modern science had concisely defined this idea in its particulars From this point he went on to describe, with the help of the films, the birth of the mosquito, its infection and the transference of this to the human being, while the rest of the lecture graphically described the measures which Italy has devised to fight the disease and which have given that country the most thorough anti-malarial legislation in the world In 1887, said the lecturer, there were 21,000 deaths from malaria in the whole population of Italy—namely 71 per 100,000, to-day the deaths are about 5 per 100,000; malaria is practically on its way to disappearing from the country At the close of the lecture a telegram was sent to the Italian Ministry of the Interior conveying an admiration of Italy's splendid work on the part of British science

THE TEACHING OF SWIMMING

To the Editor of The Lancet

Sir,—The letter from Mr Walter Edmunds which appeared in your issue of June 19th, was both interesting and timely But when Mr Edmunds says that "the education authorities do not undertake the teaching of swimming," I think he cannot be aware of what is being done not only in his own neighbourhood of Putney but all over London elementary schools

Swimming *is* taught in London elementary schools Though it is not an obligatory subject of the curriculum, the great majority of schools send pupils to the baths during school hours In a report which my committee presented to the Council last July it is shown that about 94,000 boys and 60,000 girls—i e, about 75 per cent of the total number of pupils of 11 years and upwards—are receiving instruction in swimming each year Some 21,000 boys and 15,000 girls, unable to swim at the beginning, are able to swim at the end of the season, and it is reckoned that approximately four out of every five boys and one out of every two girls leaving elementary schools have been taught to swim under the Council's scheme As a rule, the boys are taught by their class teachers, but for the girls special instructresses are engaged Over 50 public baths, together with three baths under the control of the Education Committee, are used during the summer practically every day in the school week by classes from elementary schools, many of which continue to take swimming throughout the winter

The flourishing position which swimming has attained in the London elementary school system is due in a large measure to the energies of the London Schools Swimming Association, a central association of teachers working in a voluntary capacity, which coördinates the efforts of the local schools swimming associations in directing the out-of-school swimming activities of the children This Association organises annual galas and competitions, publishes books of instruction, and conducts examinations Last year, under the auspices of the Association, no less than 8500 boys received certificates for being able to swim 100 yards and 8000 girls for swimming 50 yards, while over 7000 children were awarded certificates for life-saving

I can only speak of the schools maintained by the London County Council, but in justice to my committee and to the teachers who, both individually and through their associations have been so successful in developing the instruction in swimming, I feel I ought to put these facts before Mr Edmunds and your other readers

I am, Sir, yours faithfully,

W H Webbe,

Chairman of the London County Council
Education Committee

County Hall, London, S E, July 12th, 1926

THE PANEL DOCTOR'S WAITING-ROOM

A correspondent has addressed us on the possibility of panel patients in doctors' waiting-rooms proving dangerous foci of infection He declares that men, women, and children are herded in these rooms sometimes for hours and that while some have little the matter with them, others may be in the most infectious stage of diphtheria or measles In many cases, he adds, the waiting-room is badly ventilated, and the patients waiting attention vary in degrees of cleanliness

We must demur at the suggestion that patients are kept waiting for long periods in overcrowded and unhygienic waiting-rooms Great efforts have been made to ensure that panel patients are seen as promptly as possible, and very large panels are now exceptional unless the practitioner has partners The public have, moreover, been educated to recognise the possible significance of a rash or a sore throat, and seldom bring a really sick child to a waiting-room for diagnosis Our correspondent may feel assured that while this method of spread of infections cannot entirely be excluded, it is not a danger to which patients are commonly exposed

THE "PURA" TEAPOT

We have received from Messrs Joseph Gilbert and Sons, of Sun Works, Bissell-street, Birmingham, a patent teapot, devised to enable the spout to be more easily cleaned than is possible with the ordinary make At the same time spent tea-leaves are prevented from blocking up the spout and the various unpleasant accumulations are obviated This is made possible by the use of a movable strainer which slides down through a slot in the rim of the teapot and screens the large opening of the spout within the pot On removing the strainer the internal spout opening is exposed to view for the purpose of cleaning A coffee pot is also made on the same principle, and both vessels can be had in silver-plated nickel or Britannia metal, the price varying from *40s 6d* to *131s 6d* according to size, material, and pattern The invention makes for cleanliness, and these pots should prove convenient in the home and particularly desirable acquisitions for hotels and restaurants

PASTEURISATION OF LONDON'S MILK

A number of medical officers of health were amongst those present on June 29th when Lord Kenyon opened a new milk pasteurising and bottling plant at Valley Farm, Streatham

Every gallon of milk dealt with at this farm is pasteurised, bottled, and sealed without being touched by hand The milk is heated to a temperature of 145° F and held in glass-lined tanks at that temperature for 30 minutes After pasteurisation, it flows by gravity over coolers, situated in a glass-lined room into which fresh air is filtered, and thence to bottle filters and cappers In this way 25,000 gallons (250,000 bottles) of pure milk can be treated daily Two giant bottle washers have been installed, and each bottle is washed and sterilised for 20 minutes by 23 different operations Churns are subject to a similar but shorter process At a bacteriological laboratory on the premises tests are made to ensure the cleanliness and purity of the milk supplied to the consumer

Lord Kenyon, in performing the opening ceremony, congratulated the United Dairies on the excellence of the new depôt's equipment He was, he said, chairman of an Advisory Committee on Milk, and he was glad to be able to say that 90 per cent of the milk drunk in London was pasteurised He looked forward to seeing it all so treated Mr J H Maggs chairman of the United Dairies Ltd, claimed that the milk trade was now in advance of legislation, and remarked that if medical officers of health could move the Legislature to further action the United Dairies would not complain

Guy's Hospital Dental School—Mr Francis Dyke Acland, Chairman of the Dental Board of the United Kingdom, last week opened an extension of the dental school of Guy's Hospital which has cost £23,000, £5000 of it contributed by the Dental Board When the school was opened in 1889 approximately 4000 patients attended - last year the number was 84,000 The number of students enrolled exceeds 2000

An Address

ON THE

MEDICAL PRACTITIONER AND THE PUBLIC.

Being the Presidential Address delivered at the Annual Meeting of the British Medical Association at Nottingham, on Tuesday, July 20th,

BY ROBERT GEORGE HOGARTH, C.B.E., F.R.C.S. ENG.,
SENIOR SURGEON, GENERAL HOSPITAL, NOTTINGHAM

[THE President commenced by expressing his heartfelt appreciation of the honour done him by his election, and by calling attention to the march of medical science as expressed by the great decrease in the general rate of mortality during the last 50 years. He continued :—]

Far more desirable than to make a brave show in the statistical tables and increase the number of nonagenarians and centenarians is to raise the general standard of health among all ages of the community. Let us look at this question from the point of view of the State, since our duty to the State, according to some people, seems to be reckoned higher than our duty to ourselves. During the war public opinion was shocked to discover that the C3 category was so large in comparison, not with the A1, but with the B's and even with the C's. But it did not surprise the doctors, who knew the long catalogue of disabling ailments which afflict the general mass of the people.

The first sets of figures published by those who medically examined the school-children in the elementary schools had already given clear warning. If such distressing percentages prevailed among the children between the ages of 5 and 15, what was to be expected when they grew to manhood? Moreover, a swollen C3 category of men between 18 and 45 necessarily means a still larger percentage of the same category between 45 and 65, after which year, presumably, very few of these damaged people contrive to earn a livelihood. What is true of the men applies no less to the women, and so we have throughout the country an enormous mass of bruised and damaged humanity which never enjoys robust health, which is continually ailing, which provides a multitude of victims for every epidemic, and which, regarded from the purely economic standpoint, never approaches full industrial efficiency, because it is never fit and alert.

I would not paint the picture in too sombre colours. Most of the world's work is routine work, which can be got through more or less satisfactorily at ordinary times whether, for the purpose of the military category, a man is classed C3 or B2. Nevertheless, the C3 man will be oftener on the sick list: he will make more mistakes; he will produce less; he will lose his job sooner; and at any moment of emergency he will be less trustworthy and reliable. His physical deficiencies will increase with the passing years; he will be less able to protect himself and his family; he is more likely to seek support or stimulant from alcohol and then begin to suffer from its cumulative effect. Would it not therefore be better for the State if we took pride, not in rewriting the tables of mortality, but in raising the C3 people to a higher category—not in view of distant military contingencies, but for the immediate purpose of rendering them more efficient citizens, more valuable producers of wealth, parents of a healthier stock, and themselves more contented with their lot.

If we regard the great stagnant pools of ill-health and the infinite variety of debilitating ailments, deep-seated and chronic, we are driven to the conclusion that physical inefficiency is at once the most permanent and fruitful cause of individual unhappiness and social discontent.

Walt Whitman's lines are worth recalling in this connexion:

> "I think I could turn and live with animals, they are so placid and self-contained;
> I stand and look at them long and long.
> They do not sweat and whine about their condition,
> They do not lie awake in the dark and weep for their sins . .
> *Not one is dissatisfied—not one is demented with the mania of owning things .*
> Not one is respectable or industrious over the whole earth."

Humans are like animals at least in this, that if they are to be happy and contented they must either keep fit or be kept fit; and the honour of being considered the greatest benefactor to mankind belongs not, as is so often said, to him who can make two blades of grass grow where only one grew before, but to him who can add most to the science of health and raise the standard of fitness throughout the whole community. Surely that would be of more instant value to the State than the preservation of infant life in the first year of existence and the indefinite prolongation of what used to be called the allotted span. If there be any who dislike such a comparison of human values, they may be reassured by the reflection that whatever measures are taken to raise the general standard of life can hardly fail to benefit the infant in the cradle and the aged patient in the Poor-law infirmary.

THE STATE AND THE NATION'S HEALTH: PREVENTIVE LEGISLATION

If these considerations have weight, it must be one of the paramount duties of the State to concern itself more and more intimately with the health of the nation. It can do that by its solicitude for those who are sick, and by taking whatever measures are possible to keep them from becoming sick. Its action, in a word, must be both curative and preventive. While the science of medicine was mainly empirical and the causes of disease were either unknown or wrongly attributed, preventive measures by the State were little thought of. To-day a long series of Public Health Acts and the still recent creation of a Ministry of Health attest the full recognition and acceptance by the State of this essential administrative function. The right of the State and of the public authority to invade this particular domain is no longer challenged. It is seen to be for the common good that the sanitary and the factory inspector are armed with the sanction of the public authority; and as the ameliorative possibilities, latent in preventive measures are better understood, there will be a growing impatience with the obstacles placed in their way by selfish or interested parties. The establishment of the Ministry of Health bore witness, not to the sudden discovery of a new truth, but to the proved results of much admirable work which had been done in the previous half century and to the need of its more resolute prosecution. We are now accustomed to the blessings of a pure water-supply and efficient systems of drainage and sewerage; we have grown intolerant of the most offensive features of a slum; we have a clearly defined standard of, say, the minimum hygienic requirements of a new house. Throughout the wide field of industrial hygiene we know what conditions are desirable and what are dangerous to health. Our knowledge is fairly complete; the practical difficulties are connected with administration—how to deal with the borderline cases, and how to make the best use of the money at disposal, for improvements are always costly and public expenditure can only be met either out of rates or out of taxes. Public opinion has to be educated continuously all the time. As a rule it proves amenable to tactful handling. For example, the compulsory notification of diseases is now extended far beyond its original scope to as many as 22 notifiable diseases, and will probably be extended much further within the near future. The agitation when the National Health Insurance Act was being passed is now remembered with a smile for the broken vows that were registered never to lick Mr. Lloyd George's new-fangled stamps. But even the greatest changes are very soon accepted as if they had always been,

5369

provided that on the whole the new institution functions well and promotes, in spite of whatever defects, the general well-being

The scope of preventive legislation is almost limitless, and we are likely to see the State interfering —or shall I say intervening?—more and more in the interests of public health For example all the Licensing Acts of the last half-century are based in the last instance on the argument that stricter regulation is necessary for the general public health and safety, and it is obvious that that particular field of controversial legislation is by no means exhausted Moreover, the State is beginning to assert its regulative powers in departments of social and even of family life from which hitherto it has held aloof, and its justification will always be that the interests of public health override the personal interest of the individual, who, as a member of the community, does not and cannot act to himself alone We may expect sharp controversy, for example, if and when the State concerns itself directly with eugenics, and asserts its solicitude for a generation not yet born, not by the provision of cradles and nurseries, but even by the very determination of parentage itself This might have seemed fantastic a few years ago But now that the idol of State socialism has been set up for our worship, we may be sure that sooner or later the theorists will attempt to invest the Ministry of Health with increasingly autocratic powers, and will seek to transform the whole medical service of this country into a State service, with State hospitals, State examinations for degrees, and the State payment of doctors This would be a perfectly logical development in a socialist State, nor can it be pretended that such a system could not be worked But whether it would be as efficient as our present system, whether it would be as acceptable to the general body of the people, and whether the vastly increased cost would be repaid by equivalent advancement of medical knowledge or improvement in the public health, there is room for the very gravest doubts

DOCTOR AND PATIENT

The patient's right to choose his medical adviser—which right is indispensable to the creation of a perfect relationship between them—has contributed largely to the smooth working of the National Health Insurance Act There are roughly 13 million insured persons and rather more than 13,000 medical practitioners on the panels These are not, as some ill-informed critics of the service would seem to assume, a separate and inferior class of medical men They are in every sense of the word general practitioners, and the service they give is a general practitioner's service

To each patient on his list the insurance practitioner accepts the relationship of a family doctor, just as he would do if he were called in by a private patient He gives to each the skill and the attention within his power, and he gives them, as a rule, cheerfully and willingly, as he has contracted to do One sometimes hears general complaints of too rapid and casual a diagnosis, but when the waiting-room is full the same complaints are not wholly unheard even in the most august thoroughfares of the London specialists The true test of value of the service given is to be found in the fact that in 1924 only 404 complaints were received by insurance committees and investigated by their expert subcommittees, and in only four cases did the more serious charges result in the removal of the practitioners' names from the Medical List

Is it likely that a better service would be provided if each insurance practitioner were selected for inclusion in the list by some official of the Ministry of Health and if he were required to give an even more detailed and minute account of his practice and submit still more voluminous reports? The panel would still be composed of exactly the same people, and even if the allotted quota of patients were reduced, is it at all certain that the individual patient would receive a greater share of the doctor's attention?

We know what happens in all State services The red-tape machine would soon be started, more and more reports would be called for, the doctor might see fewer patients, but the volume of his activities would be in no wise lessened, and the cost of the service to the taxpayer would be enormously increased You will not make the panel doctor a better doctor by making him more of a civil servant and less of a doctor, nor will you make the 13 million patients more contented with their treatment

The reform that is most required in connexion with the insurance service is one which shall link up the insurance practitioner with the consultant physician and the consultant surgeon, and give the insured patient the benefit of the profession's specialised as well as of its general knowledge

HOSPITALS AND THE STATE THE VOLUNTARY HOSPITALS

Nowhere is the principle of voluntaryism so well worth maintaining as in connexion with the hospitals, nowhere has it been so triumphantly maintained It is sometimes suggested that the chief virtue of voluntary agencies is to do the rough pioneer work in difficult and intractable places, to create a favourable public opinion, and then, in due process of time, to hand over control to some department of State which will carry on the work upon an altogether larger scale Indeed, I have seen it stated that voluntaryists ought to be proud to merge their small individualities into the larger being of a public department and to lose themselves like rivers in the sea But the enthusiastic friends of the voluntary hospitals are human beings, not mere charitable machines which function altruistically because their well-disciplined hearts happen to be set that way They are proud of their work They love it They see results which encourage and inspire them They do not want to sink themselves, but to express themselves The gratitude of those who are healed is sweet in their ears Voluntaryism is the very life and soul of the whole hospital movement It is not suggested that the hospitals would wither if the voluntary principle were abandoned They would still multiply and prosper Their orderly routine might well show an even more brilliant and imposing efficiency But the rules and regulations would lengthen The spirit of the institution would suffer change and lose something —I fear much—of its geniality and kindliness Why is it that such a difference exists to-day between the voluntary hospital and the Poor-law infirmary, which is often better constructed and much better equipped? If you ask a patient to which he would rather be sent, why does he always say the hospital? To some extent the old hard, unforgettable associations and traditions of the Poor-law still chill the heart. But that is not the whole truth There is something inherent in officialdom which freezes the genial current of the soul, and thaw it as you will by the application of whatever new principles of kindliness and mercy, it can never be thawed right out

Let us stand by the principle of voluntaryism in the hospitals at whatever cost of energy and patience required for their adequate provision and efficient maintenance I need not remind this audience that it will take a vast and sustained effort to provide the 10,000 additional beds which the Voluntary Hospitals Commission has declared to be necessary For that effort the friends of the hospitals will soon have to brace themselves There is to be no financial assistance from the State The Minister of Health last February very reluctantly came to the conclusion that no subvention was possible, at any rate at the moment, and so the hope that the Government might repeat its unconditional grant of half a million to the hospitals after the war, in recognition of their invaluable war work and of the utter impossibility during the war period of keeping abreast of their requirements, has been cast to the ground Unless this second grant had been as unconditional as the first I do not know that I am altogether sorry at the Government s decision. If the Ministry had begun to impose conditions of control it might well have marked the beginning of the end of the voluntary system I contend that the work done by the hospitals is of such inestimable value, and the confidence placed in them by the public is so well justified that the State if it makes any subvention at all should do so without restrictions, knowing that the money will be judiciously expended. The hospitals should beware of even the mildest beginnings of State control and the relentless, however friendly. grip of any State department However, as there is to be no grant these particular anxieties do not arise and the supporters of the hospitals must shoulder their burden So large a sum as 4 or 5 millions for new capital expenditure will take a very considerable time to raise; for. over and above all this the maintenance cost has to be found for each new bed provided, and this means an additional recurrent annual cost of £148 per bed Many of us were disappointed that once again the Chancellor of the Exchequer in the last Budget failed to exempt bequests to hospitals from liability to legacy duty. That is claimed as an act rather of justice than of grace The toll taken by the State is an interception of charity which is repugnant to good feeling and a sense of fair play to the suffering The hospitals, of course, in their turn. owe to their generous supporters the duty of sound economic management, which in turn depends primarily upon the choice of governors Those which show the best financial balance sheets usually have upon their board of management some outstanding figure of marked ability who has made the local hospital his hobby. his interest, his care and his pride However that may be, there must be the undoubted assurance of economic and prudent management if the full support of the public is to be continued It may well be that a closer coöperation between hospitals—large and small, general and special—is possible and desirable and that considerable economies might be effected without infringing the real autonomy of each institution, which is so properly and jealously guarded Charitable effort in this country has always been specially subject to the besetting sin of overlapping and wasteful management; voluntaryists must be ready to face a searching criticism of their accounts by business men whom, if they are wise they will invite and welcome to their councils

CHANGING TYPE OF HOSPITAL PATIENT

The hospital is no longer the lazar-house of the destitute the place to which homeless and plague-stricken outcasts crawled to die or into which they were herded if they seemed too noisome and dangerous to be tolerated at large Such it was in mediæval times; then came the period, which lasted more or less down to our own day, when the hospital was still exclusively used by such as were too poor to pay for the ministrations of a doctor. Some people still hold that this should be the fundamental function of any hospital which is supported by public subscriptions, and I agree that this primary purpose for which hospitals exist—namely that of taking in and caring for the indigent poor—must in no way be shelved or neglected But we have advanced far beyond that simple conception in these days, and we shall advance much further still if only because the hospitals from being mere infirmaries have become the centres of the best medical and surgical skill in the areas they serve The best nursing the latest scientific apparatus all are concentrated there for the service of the poor, and while the rich and the well-to-do can look after themselves there remain large intermediary classes of the population who are cut off from the best skill because on the one hand, they cannot afford the fees and on the other they are not of the class for which the hospitals were intended If that were pressed it would indeed be intolerable especially in view of the increasing expensiveness of any serious operation or illness the cost of nursing homes and the palpable unfairness of leaving out in the cold the great body of the middle classes. whose financial betterment has by no means kept pace with that of the superior artisan class, and who have been in the past according to their means, good and loyal friends of the hospitals.

Wards for Paying Patients

It is certain. therefore, in my opinion. that we shall see a steady extension of the principle of the paying ward, and even of the paying hospital for the use of the patient who pays in accordance with his means. In many hospitals to-day all but the very poorest patients are expected to contribute to the cost of their healing, and there is little need to lament the disappearance of the old principle that the hospitals were absolutely free—a principle which. in fact was often grossly abused The interests of the middle classes deserve attention no less than those of any other class May we not therefore look forward to a time when every general hospital will be well equipped with paying wards or will have a paying hospital in association with it, served by the same staff and the same nurses? A middle-class patient who is a suitable hospital case could be seen by the almoner of the hospital and, after stating his income and position terms could be arranged according to means Naturally that will open up the question of fees for the surgeon or the physician and some obvious and possibly difficult adjustments would have to be made: but no vital principle that I can see would be endangered by the payment of these special fees or even by the hospital itself making a substantial profit on such cases which would help towards the maintenance of more beds in the non-paying wards Such changes are likely to be gradual; we can carefully note what effect. if any. they have upon the flow of subscriptions Personally. I do not think that the charitable donor is likely to object to a middle-class paying patient receiving a share of the fruits of his bounty He had a much more valid grievance against those who abused the freedom of the hospital and never contributed a penny to its funds The medical profession is generous in accommodating its fees according to the patient s income But every medical man knows cases where the serious illness of the bread-winner or the wife or child has exhausted the savings of a middle-class home or crippled it with a load of debt. The middle-class patient moreover. is the principal sufferer from the high fees of the nursing home another institution which has a necessary place in our existing system for dealing with the cure of disease but which is by no means immune from well justified criticism Is it. indeed too much to say that the extreme expensiveness of nursing homes—I speak of course. in purely general terms—is contributing as much as anything else to the extension of the system of paying wards in hospitals and the call for its rapid development.

Working-Class Contributions to Hospitals

There is also another important development in process with regard to the hospitals. More and more in the large cities and industrial areas the hospitals are coming to rely upon the subscriptions of the working classes, contributed through a general hospital Sunday collection or through a direct trade union levy In this district for example the Hospital Saturday Committee are very good friends of the hospitals contributing willingly. cheerfully, and without condition or stipulation as to the hospital service for their members they will receive in return This trust is not misplaced They lose nothing by not dealing in terms of contract and demanding the strict recognition of a right Many county hospitals are stimulating interest in their work by forming a collecting committee in every village and persuading the cottagers to subscribe to its funds almost in the same way that they subscribe to a sick or benefit club This will necessarily lead to a great extension of the hospitals for those who pay will expect to receive hospital treatment as *a right* in case of serious illness When the small contributor begins to talk about "our hospital," the vitalising spirit of voluntaryism is at work Open the door to State direction and control and the cold east wind of officialism will contrive an entrance too.

THE GENERAL MEDICAL COUNCIL

Another aspect of the relationship of the medical profession to the public has been much discussed of late in connexion with certain punitive action taken by the General Medical Council This discussion has removed many misconceptions as to the specific purposes for which the Council was created by the Legislature—not, as was too often supposed, to serve as the executive of a powerful professional organisation protecting the interests of its members but as a body entrusted with powers, clearly defined first by Parliament and later by the judges, for the protection of the public against the incompetence and the imposture of unqualified medical practitioners Practically the only criticism directed against the Council rises from the fidelity with which, in these days of growing laxity, it has maintained its jealous regard for the purity of its register of membership There are really two main questions in which the lay public is interested The first is Is it or is it not to the public advantage that the General Medical Council should set its face like flint against professional self-advertisement? The second is Is it or is it not to the public advantage that the Council should show a less uncompromising attitude towards the unqualified practitioner and a greater leniency towards those who transgress its stringent rule against covering?

The rule against professional self-advertisement is unquestionably in the public interest The publicity agents of the commercial world may sound their slogan as they will about "Truth in advertising" But, as Dr. Johnson once shrewdly observed, the secret of advertising is "large promise"; and large, limitless, boundless promise is wholly out of place in the practice of the medical art Inseparable from quackery, it is the sign manual of the unqualified nostrum-monger In my view, this most salutary rule against professional self-advertisement needs to be observed more than ever now that the old reticences are being broken down in so many directions, and in view of the growing disposition to discuss all medical subjects freely in the public press

Whether we like it or not, that school of thought is prevailing which holds that the open forum is the best of all popular educators, that ignorance is the greatest of all dangers, and that publicity alone can create the new public opinion out of which it is hoped there may issue a higher moral sense and a stronger self-control The public press will devote more and more space to the manifold problems of public health, and it is obviously desirable that what is written should be written with authority No anonymous article on a technical or professional subject carries the weight of the signed contribution, and if doctors write for the lay press, as they will be urged to do with an ever-increasing insistence, the opportunities of professional self-advertisement will greatly multiply.

Nevertheless, it is to the common interest of the profession and of the public that these temptations —not, indeed, to inform the public of what is for its good, but to inform it in such a way as to advertise and glorify the writer and conduce to his personal gain —shall be resisted, and that the Medical Council shall still continue to exercise its powerful restraints In other countries a different practice may be followed, but till it is shown that their method is more conducive than ours, either to the dignity and character of the profession or to the protection of the public from the charlatan and the quack, these restraints should not be weakened. Many borderline cases are bound to occur as they do at present, but I assume that the Council will continue to act with that judicial discretion which has on several occasions received the acknowledgment of the highest legal authorities

UNQUALIFIED PRACTITIONERS

As for the unqualified practitioner, I say without hesitation that the Medical Council cannot and must not recognise him, and therefore cannot and must not abate its strong reprobation of covering To do so would be to stultify itself and the Register, which is its special creation and instrument It cannot, to borrow an expression from another profession, recognise any orders but its own. I do not mean that it should seek to induce the State, as is done in some countries, to make unqualified practice illegal Even if that were desirable, the public would not permit it Public opinion, if I may say so, has a sporting fancy for the outsider, and outsiders, even the rankest, do sometimes win But, though rare and exceptional cases may arise, the Council cannot extend either the bow of friendship or the nod of recognition to any unqualified practitioner without placing itself in a false position If an unqualified practitioner really discovers a new cure or treatment for one of the ills of humanity, his consulting room will not long remain empty of patients If his method is genuine it will endure, and, soon or late, it will win general recognition But no one can reasonably expect admission to the Medical Register—or to any appendix thereto—by any except the approved channel Admission is not a question of initiation and secret rite, it is a plain question whether the entrant has gone through certain courses of medical training and passed the presented examinations How can either be abandoned with safety to the public interest? The unqualified practitioner may or may not have sufficient general medical knowledge to enable him to make a diagnosis A few may have gone through some sort of a medical course, the majority have not It takes the ordinary medical man five years or more to complete his course, the unqualified man often does not give as many months He professes to be a specialist without even elementary grounding in the essential rudiments of medical knowledge I say nothing against the science of osteopathy or these uses of the manipulative treatment I only say that those who practise these arts should have the medical knowledge without which they may do their patients infinite harm

The champions of the unqualified practitioner fall into two main classes One consists of those good people, invincibly credulous and optimistic by nature, who chatter about cures and treatment as others chatter about politics, and on whose ears well-syllabled words like "osteopathy" and "manipulation" fall with a sweetly modulated cadence of solace and hope The other class consists of the ingenious rebels against all authority but their own, the sophists of the day, who deride professional etiquette and grimace at professional tradition Perhaps here and there certain solemn pomposities do linger even yet in our profession, and an occasional grin at these may do no harm, but the health of the public is no grinning matter. The plain truth remains that behind the rare—the very rare—unqualified practitioners of whose success so much is made, but whose failures pass unrecorded, there are scores of other practitioners of technique ancient and modern, Chaldean and transatlantic, who are eager to take advantage of any momentary opening of the door, which it is the declared policy of the General Medical Council to keep tightly shut A selfish, obscurantist policy would be totally contrary to the free spirit of inquiry which animates the medical science of to-day But this is neither selfish nor obscurantist Whatever in any modern technique is tested and proved good is sure of eventual adoption, and not even the gates of the General Medical Council will prevail against it But the tests and the proofs must be such as are recognised by that universal medical science which talks a common language throughout the world and which alone can securely judge The public mind was, perhaps, never more impatient of authority than it is to-day Unable to distinguish with certainty where the trained expert alone has any claim to be heard, multitudes of people are still prepared to accept offhand the morning and the evening stunt of their favourite newspapers, which are then forgotten as soon as read So many romantic impossibilities of yesterday have become the casual scientific commonplace of to-day that the very word "miracle" itself has shrunk back to its original connotation, and even the wisest have still no effective retort to Hamlet's gibe as to the inadequacy of their philosophy to embrace the content of heaven and earth Nevertheless, Authority remains unshaken on her intellectual throne, though the gusts of change may a little disorder her raiment, and Authority herself acquires a riper wisdom and a larger experience with the passage of the years

The medical profession is a living profession It is for ever breaking new ground, mapping and charting as it goes, and the necessary correction of a too hasty observation or faulty induction, as well as the need to include new knowledge, requires us from time to time to revise our atlases And though we may be fairly confident that the older continents are now accurately charted, there is always the need to be prepared for the crash of old-established notions and for restless movements of insurgence along boundaries which once appeared to have been fixed for all time It is a sobering reflection that, but for the violent wrench out of its true direction which medical science suffered two thousand years ago, some of our most recent discoveries might well have been among the oldest blessings to suffering humanity. With the abandonment of the one true scientific method of patient observation and careful induction there was also unhappily discarded that sagest of all the medical maxims of ancient Hellas, that the physician is the servant of Nature The human race has suffered sorely because medical art and science took so tragically wrong a turning, after making so brilliant a start Probably the perversity of the patient was largely responsible Popular demand has always been insistent for the bottle of medicine and the charm Science, under the lead of Aristotle, had sought to exorcise the potion-monger and the thaumaturgist, but back they came with a rush, and when the ancient scientist candidly admitted that he was uncertain as to the nature or the cure of the complaint, the patient soon betook himself to one who promised a safe, quick, and pleasant cure

The great truth that the supernatural and the scientific do not run well in double harness needs, I believe, a resonant restatement to-day. The profession is often blamed for its instinctive repugnance to the introduction of the supernatural into the art of healing This is attributed to that professional jealousy which is supposed to seize every doctor when an unregistered hand assumes the gold-headed cane which is the symbol of his craft I do not know that there is more professional jealousy among doctors than there is among lawyers; I doubt if there is as much as among plumbers and bricklayers No professional body loves an outsider who usurps its own particular functions, and long experience has shown that the unqualified practitioner of medicine is in double measure an unqualified danger to the public And yet how clients troop to his door or run in upon him a shower of post-office orders if he is a shrewd exploiter at once of the foibles and the earnest longings of mankind So it has ever been, so it will ever be As the cynic long ago said "If the public want to be deceived, let them" But the obvious fact is that the public want not to be deceived but to be cured, and that is why, if an authorised prescription in our cryptic Latin fails to bring relief they will cheerfully take a free medical tip in plain English from their Sunday paper's answers to correspondents, or accept as gospel the large promise of displayed advertisement, or if they are of a more serious and contemplative type, they will haunt the temples of those who say that they possess the secret of permanent good health.

THE RELIGIOUS HEALER.

With respect to the religious and quasi-religious healer, the medical profession is in a difficult position. It is precluded by the memory of its own empirical past from adorning its robes with the fragile fringes of infallibility Dedicated to science and conscious of boundless horizons still beyond its ken, whatever face the profession may present to the outer world, it must display in the intimate presence of truth the modesty of the neophyte Nor can it refuse to acknowledge the sincerity of other searchers after truth travelling upon roads other than that on which its own feet are set Nevertheless, the profession owes to itself and to the public the duty of speaking out.

There is no difficulty, of course, in dealing with the vulgar quack who sells a bottled panacea to the joint benefit of himself and the Inland Revenue, and who leaves the deluded purchaser, if he be lucky, much the same as he was before But obvious difficulty arises when a new theory and practice of the art of healing is proclaimed and health is taught in terms of religion, and religion in terms of health In that company the medical scientist has no place His facts are not theirs Their terminology is not his. There is no meeting ground in common He knows what he understands by science; he does not know what they mean Even if he were willing to join the new cult, its complete refusal to recognise the need of a medical art, such as that which he practises, must effectually keep the door of communication closed Science has long since framed her own laws of method and proof which are recognised throughout the world, and the medical profession can have no commerce with any newly organised cult which denies the very bases on which these laws are founded. But this is not to say that no friendly cooperation is possible between doctors and those who are earnestly studying the healing power of the mind. Let there be no contention about names, when we speak of mind or soul, let us freely admit that we cannot take a specimen of either on a slide and put it under a microscope. That there is a certain healing power, a true *vis medicatrix*, in religion as in nature, few careful observers would, I think, deny Between religion and nature, between mind and body, there exists not an opposition but a relation. Every medical man of experience must have known cases in which his own scientific skill has seemed to be helped, sometimes most strangely and wonderfully, by some serenity of mind in the patient, some quiet confidence in the ultimate issue, some realisation of sure dependence upon a higher power, some tranquillising influence of the soul upon the physical stress and tumult of the senses—beneficent, soothing, healing activities in which he and his art have had little or no share.

These facts are not reducible to formulæ Science cannot explain them as she can explain the operation of an anodyne stealing along the passage ways of sense We do not, indeed, know very much about that mysterious parallel road, which always lies in deep shadow, where the mind or the soul, reacting to a spirit which seems to come from without, influences profoundly in its turn the body which the doctor is trying to heal There is no place in respect of this region for dogmatic utterance; but there is always room for patient and reverent inquiry. The whole of our profession will await with impartial mind the result of the labours of the joint committee which was appointed some months ago to investigate the phenomena of what is generally called spiritual healing Meanwhile, I say with confidence that any systematised creed which professes to dispense with the art of medicine and surgery is false to the Divine. But if any possess the precious gift of ministering to the mind diseased or of imparting to those who walk in the shadow of the valley the courage to move serenely among the phantoms and terrors which haunt that road, let us be sure that so divine a gift can only emanate from a divine source, and let us welcome the help of any unseen wings that stir the air with healing. In such moments the old tradition is confirmed that the doctor stands in a different relation to his fellow from most other professional men I do not claim that the doctor consciously lives, like the priest, what is called a dedicated life—though I have known men to whom that noble phrase might well be applied—but there is a special nexus between doctor and patient which is independent of, as it is unpurchased by, the fee which passes between them The public expect much of the doctor and take much for granted I like that old story of the woman of Selkirk who, observing her doctor ride by, said to the neighbour with whom she was gossiping, "Aye, there goes the doctor—honest man! He's brought all my ten bairns into the world and never got a rap for one of them"

The Real Doctor

The national health insurance scheme has at any rate checked the more unconscionable draughts which once used to be made upon the deep well of medical disinterestedness, but the profession still gives much for which it receives no direct return but gratitude, and sometimes even that is left unspoken That, however, is the penalty of altruism and an established reputation for kindness of heart, and that is partly why the doctor holds his place in the public esteem, despite the satirists, the playwrights, and the novelists who still delight to poke their fun—on the whole not unfriendly—at his etiquette, his bedside manner, his scraps of weird Latinity, and the artifice with which the wild surmise of an impossible diagnosis may still be masked under the grave, slow smile of apparently assumed certainty

If we want the portrait of the real doctor we go, not to books, but to life We expect him, not in vain, to combine with knowledge the understanding that springs from intuition till it is most richly reinforced by experience, to bear a tranquillising influence, and to radiate confidence and hope We expect him to exemplify, like the surgeon of whom Henley wrote

> "Faultless patience and unyielding will
> Beautiful gentleness and splendid skill,"

caring always for life as a thing most precious, quick—and now happily well able—to spare the sufferer one unnecessary pang, the restorer of health, a strong sure help in the more supreme moments

> "In many a house of care, when pain has forced a footing there
> And there's a Darkness on the stair will not be turned away"

Such is the doctor, the family doctor, who is more to the public at large than the most learned and the most wise who dwell in those two long, unlovely, parallel streets of London, where the waters of healing are laid on at the main He is still the same, even though he is called upon in these days to enter the service—the preventive service—of the Ministry of Health, disarming disease before it strikes, saving the firstborn, not by a smear of blood on the lintel, but by a dash of disinfectant in the drain, and sometimes purchasing the immunity of millions as cheaply as the restoration of a few convalescents to health The doctor's professional qualifications may change as medical science advances, the qualifications he needs to win him the confidence of his fellows are unchangeable as human nature itself That confidence it is the policy of this great Association and the desire of every one of its members always to deserve and for ever to retain

---

Founders of Westminster Hospital — On July 14th the Lord Chancellor, Lord Cave, unveiled at Westminster Hospital a tablet recording the names of the founders in 1719, and of the presidents, chairmen, and treasurers at the time of its erection on the present site in 1834, and of its reconstruction in 1923–24 The original founders were Henry Hoare, William Wogan, Robert Whitham, Patrick Cockburn, and Thomas Wisdome The Hoare family have continued to be closely connected with the hospital, but no descendants of the other founders have been traced

An Address
ON
PROGRESS IN PSYCHIATRY

Delivered before the Section of Psychiatry, Royal Society of Medicine

By R H COLE, M D, F R C P Lond,

PHYSICIAN FOR MENTAL DISEASES, ST MARY'S HOSPITAL, LONDON, PRESIDENT OF THE SECTION

The practice of psychiatry is partly science, partly art It is not unlike war, where the unchanging principles of strategy are but little influenced by the ever-progressing science of tactics The pathology and treatment of the insane make steady strides, while the problems presented by the relationship of law and public opinion to disordered conduct seem to remain remarkably constant, and require adjustment by successive generations I am able to recall changes and progress in the medical aspects of psychiatry, while I find a recurrence to-day of many ethical and legal questions which were being raised in similar terms when psychiatry first claimed my attention From the days of my boyhood I was interested in that ancient institution at Hanwell, by reason of its proximity to my home When I began practice over three decades ago, London was a city of hansoms and horse 'buses, motor-cars were a joke, houses were mainly lit by gas, and the telephone was an uncertain luxury Flight in heavier than air machines was scarcely dreamed of outside the laboratories of scientific folk, and the gramophone and wireless were still far from finding a place in every home I should like to remind you of some of the dominating figures in our specialty at that period Their names will aid me in outlining the position of psychiatry and its handmaiden psychology, in the days to which I refer I shall then proceed to indicate some of the steps that I consider to have been the most important advances during my professional life, and the influences they are likely to exert on the future In Britain we had Maudsley, Blandford, Hack Tuke, Savage, and Clouston, all of whom were in active work I had the good fortune to be closely associated with Maudsley during my early days, and I could dilate at length upon the sayings of this remarkable sage Mercier was commencing a steady output of valuable writings, which are now, I regret to think, too little studied Crichton-Browne was already renowned as an orator, and him we happily have with us to-day The late Clifford Allbutt became a member of the Lunacy Commission, now the Board of Control, and the present Lunacy Acts were coming into operation, not without some travail to the psychiatrists of the day

Both psychiatry and psychology were on the eve of great developments The French school was pushing hypnotism, and was sharply divided by Bernheim at Nancy, and Charcot in Paris, both of which centres I proceeded to visit The subject of hypnotism was very much in evidence at home, and was investigated by a committee of the British Medical Association Extensive claims were being made for the future of this method of treatment, but in England, Germany, and America it was not found to be of great use in the psychoses, though its value was recognised when applied to hysteria G M Robertson of Edinburgh, and Percy Smith in London did a great deal to give hypnotism its proper place as a means of treatment The interest in hypnotism was very wide and had far-reaching results It acted as a stimulus to many who were, like myself, confronted with mental phenomena that seemed to have little or no explanation

Early Difficulties in the Study of Psychiatry

Let me give you some idea of the perplexity of a young medical man who wished to engage in psychiatry in the times of which I am now speaking Medical students still "walked" the London hospitals, though it was necessary to hold clinical clerkships and dresserships before being admitted to the final examinations At my own hospital, as with many others, no lectures were given on psychological medicine, the subject being for the most part lightly dealt with from the medico-legal standpoint by the lecturer on forensic medicine Many of us qualified without ever having seen a clinical demonstration, though some of us attempted to remedy matters by attending Bethlem or St Luke's Hospital

Psychology was a closed book, and was regarded as a subject for philosophers and divines, and outside the scope of medicine As a consequence a medical man took up an asylum appointment with a sublime ignorance of the mental maladies of the patients he was to treat, and the novel clinical material was at first confusing and disheartening Psychology was then focused on the cognitive aspect of mental processes The older methods of introspection had been modified by the experimental psychologists. Weber and Fechner had originated psycho-physical researches Helmholtz had given us his fine work on sensation Wundt was still absorbed in research along experimental lines The purely academic student still perused the writings of Mill, Spencer Sully, and others, though the classical text-book of William James in America soon became the standard work after its publication in 1890 Psychology almost seemed to deserve the epithets hurled at it by the energetic young psychiatrist It did little to assist him in his special study, and seemed remote from human affairs

Psychiatry was almost as sterile, although Maudsley Clouston, and Savage did much to awaken it by their stimulating writings Clinical descriptions in the text-books of the times were good, but pathology was little understood and psycho-pathology was practically non-existent Tuke's dictionary may perhaps serve as the most useful guide to the psychiatric ideas of this era

PROGRESS IN RESEARCH ON THE NERVOUS SYSTEM.

Progress in psychiatry is closely linked with progress in psychology, and advances in many sciences beside medicine I should like to refer here to the accumulation of knowledge that has taken place in my time on the structure of the nervous system and its functions For long it was held that if enough were known of the brain and cord, the mystery of mind would be explained An immense amount of work has been done on anatomical embryological, physiological, and clinical lines to define with increasing accuracy the structure and proper functioning of the nervous system Moreover, the knowledge of the autonomic system, its functions and relation to the later cerebro-spinal system, together with the structure and biochemistry of the endocrine glands has grown in a manner which seems to leave little to be discovered with our present means of investigation

Most of this work has been done in the past three decades, and when I entered medicine a great impetus was being given to the histology of the nervous system by improved methods of staining and the development of the microscope It may serve to remind you of the scope and detail of these and allied investigations if I recall to your memory the names of workers like Hughlings Jackson, Flechsig, Mott Bolton, Elliot Smith Golgi, Gaskell Langley, Sherrington, Head, Pavlow. and many others The work of Orr and Rows on the path of infection in the nervous system by means of the lymphatic circulation was an important contribution to psychiatry, and is a fine example of the use that can be made of pathological material in mental hospitals The distinguished physiologist Sharpey Schafer has taught us much of the endocrines closely followed by the introduction of glandular therapy. It may be speculation to suggest that further progress may result from the introduction of the use of ultra-violet rays in microscopy It does seem that advance in the anatomy and physiology of the nervous system must depend upon progress in laboratory methods and the results of researches which we may expect to increase the field of the microscope and teach us more of the properties of the living cell

In spite of this work on the central nervous system we have much yet to learn to establish the physical basis of mind on a satisfactory foundation. Few will maintain that consciousness can exist without brain It has become obvious that the size quality and structure of the brain is an index of the intelligence of its possessor But we cannot yet speak of mind in terms of cerebral function with all that we have learned of the cortex, both in health and disease

NEW PSYCHOLOGICAL CONCEPTIONS

These observations bring one to the almost startling growth of fresh psychological views which have thrown new light on the mechanism of insane conduct and symptoms, and provide new hopes for the future

I regard the illuminating writings of Janet as a landmark in the progress of psychiatry. His conceptions of dissociation and his clear descriptions of the possible psycho-pathology of hysteria and psychasthenia were an inspiration to many, and merit careful study to-day His views were taken up in America by Morton Prince and others, and paved the way for the psycho-analytic movement based upon the work of Freud This movement has attracted followers all over the world and has produced an immense literature Original psycho-analytic conceptions have met with powerful opposition, some of which is reflected in the establishment of separate schools headed by Jung and Adler There are certain features of the work of Freud which are worthy of careful notice. Firstly, it is based upon clinical observations Secondly, it appears to obtain biological confirmation That is to say, it is claimed that the concept of primitive mental processes, obeying the pleasure principle, receives some support when applied to child study fairy tales, folk-lore, philology. and anthropology Further no work has done so much to attach meaning to the apparently meaningless symptoms of insanity

As I have indicated, psychology in my early days of practice was academic and attention was centred upon the intellectual aspect of consciousness The psycho-analytic and other schools have moved the interest to the field of instinct Indeed psychology has since become vitalised and brought into very close relation to psychiatry Many workers have contributed to this desirable result McDougall's work on instinct and social psychology has educated many beside the psychiatrist, so also did the work of Rivers Trotter's original enunciation of the herd instinct is a splendid contribution from a surgeon. and has done a great deal to clarify the conception of conflict in psychiatry.

Psychology is making new demands and is being applied to social as well as medical problems There has recently developed most instructive work on industrial psychology. initiated by C S Myers. His investigations into fatigue in industrialism, and the conditions which govern the output of work in factories and workshops make fascinating reading It seems to me that medical psychology has an increasing responsibility in relation to social life Not only must we be called in to place on a scientific basis the nature of occupation hours of work and repose, and proper recreation but studies are necessary on such questions as the influence of alcohol and tobacco on work, the conditions which affect sleep, and the selection of careers by the young There are yet more general questions which the psychiatrist must assist in solving Recent controversies indicate that some modern trends in art are abnormal and have a psycho-pathology of their own Changes are taking place in religious beliefs. The political world is disturbed and full of unrest'

The underlying causes are psychological and the medical psychologist should be able to elucidate them There is no end to the applications of modern psychology Why, for example, should engineers be more susceptible to Communism than miners or factory workers, as has recently been alleged ?

But to us the application of the new psychology to psychiatry is of chief importance What has it done ? What is it going to do in the future ? The answers may be summarised by the three words psycho-pathology, psychotherapy, and prevention

Psycho-pathology has been given a reincarnation It is evident that many of the novel concepts concerning the mechanism of mind are finding a permanent place in the literature of psychiatry Terms like conflict, repression, projection, sublimation, transference, and libido are familiar to us all, and provide us with fresh implements for research and treatment The causation of the psychoses has been placed in a new light, and for the first time in the history of psychiatry a scientific explanation of the bizarre conduct of the psychotic patient is available The future holds great things in store for psycho-pathology, and I venture to point out the scope for psycho-pathological research to be found in our mental hospitals The chronic type of patient has much to teach us as to the sources and development of delusions and hallucinations

Psychotherapy has advanced far during my time Its practice is capturing the attention of the general physician more and more and its place in medicine is assured Psycho-analysis is one method of several approaches to psychotherapy, but it is yet early to speak with conviction concerning the results of analysis The method seems of little use in the established psychoses No army of analysts could successfully return to normal life the chronic patients living sheltered lives in the institutions of our country As to early cases and psychoneurotics there seems to be little information available to determine whether psycho-analysis obtains better results than older methods of treatment Discussion concerning the nature and functions of the unconscious mind continues Different schools have their own methods of treatment and investigation, and seem to diverge along paths whose end is not yet in sight Some writers there are who have done great service in coordinating the somewhat confusing views and teachings of clinical psychologists Both psycho-pathology and psychotherapy in this country owe a debt to Bernard Hart, whose incisive style presents to the medical profession a well-defined picture of the psychology of insanity and its application to methods of treatment

Prevention of disease which is one of the chief aims of medicine will as regards mental disorders be augmented by the lessons of the new psychology The after-care of patients discharged from mental hospitals is receiving close attention Thirty years ago the investigation of child psychology was in its infancy. Among other developments the organised tests for intelligence have reached a high standard The last 15 years have seen great progress in the investigation, care, and treatment of defectives of all grades, though more remains to be done The teaching that the foundation of neuroses or psychoses can be laid in the first few years of a child's existence is one which requires earnest consideration The ignorance of the public concerning mental hygiene is still a serious matter, and the spread of education in such knowledge is of the utmost importance to the coming generation

General Paralysis

I return to the consideration of brain pathology, the study of general paralysis best illustrates the progress that has been made It is hard to realise that when my student days were over, the pathology of general paralysis was not yet understood The disease was mostly attributed to sexual and alcoholic excesses Some authorities described the paralytic diathesis and maintained that paretics were " born not made " Clouston at one time even used to say that paresis was a certificate of general intelligence Yet the specific origin of the disease was suspected as far back as 1857 I regard the elucidation of the pathology of general paralysis as the greatest step that has been made in cerebral pathology in my generation, for not only has the establishment of the spirochæte as the cause of paresis definitely cleared up an old problem, but the work has opened up many new questions As is almost the rule in scientific progress, the answer to one query raises a host of others Why should paresis only occur in a small percentage of syphilitics ? What is the meaning of the long latent period between infection and the onset of symptoms ? Is another factor beside the spirochæte necessary to produce the clinical entity we know as general paralysis ? Or is there a special strain of the organism responsible for the disease ? It is not yet definitely known, indeed, how the organism invades the brain, nor why the application of arsenical compounds is so disappointing when applied to nervous syphilis One cannot leave this absorbing chapter in mental pathology without mentioning the work of Sir Frederick Mott He taught the specific origin of paresis with a persistence and insight that were fully justified by the demonstration of the organism in the brain of a sufferer by Noguchi in 1911 We have gained increasing assistance in the diagnosis of the forms of syphilis of the nervous system during the last 25 years Wassermann has given us a test, which, if properly carried out, enables the presence of syphilis to be determined with certainty The new knowledge of the composition of the cerebro-spinal fluid, and its behaviour in the presence of various infections, has been of inestimable value General paralysis was always regarded as a hopeless disease, although I believe that energetic treatment by mercury and the more recent arsenical compounds invariably influenced the course of the disorder Of late years the malarial treatment has introduced new hope for the victim of paresis Men are now living comparatively normal lives who were so treated a few years ago It seems definitely established that the method applied to suitable patients gives the best chance of improvement or even recovery that medicine has yet been able to offer Looking back over 30 and more years and recalling the uncertain pathology of the disease, its subjects for the most part untreated until the inevitable end in institutions all over the world, there is no more dramatic instance of progressive triumphs in psychiatry in which clinicians and laboratory workers have happily shared

Progress in Clinical Conceptions

Noteworthy progress has been made in the improvement of our clinical conceptions, older views have been attacked, new and sound entities established Korsakow's description of the alcoholic psycho-polyneuritis was being made known over here when I first studied the literature The syndrome has stood the test of time It is now becoming uncommon, but appears at intervals and was associated with arsenic in a medico-legal case of importance which occurred a few years back Of all those writers who have taken part in the advances of clinical psychiatry, Prof Kraepelin, of Munich, has perhaps claims to the premier position He has given us the conception of the manic-depressive psychosis, and has defined the conditions now grouped under the term dementia præcox His writings are models of close observation and description Not only do we owe to him new clinical ideas, but he has done much to produce our existing system of classification Moreover, he has re-educated us in the importance of the longitudinal section in psychiatry, by his insistence on the careful study of the life-history of mental cases

Clinical conceptions are becoming once more in a state of fluidity. Increasing difficulty is being experienced in placing a patient in any definite category The puerperium, the climacterium, and the senium are being dethroned as specific factors in producing insanity More satisfactory ætiological foundations are being formed for confusional states. One of the chief difficulties of clinical description is the diversity of meanings attached to the same terms when used in different countries. An early standardisation of our nomenclature is desirable, and would mark a step forward in the psychiatric progress of the world.

PROGRESS IN THE CARE AND TREATMENT OF THE INSANE

Both care and treatment of patients have received unremitting attention during my experience of psychiatry, and I think that in some respects care has outstripped progress in treatment. As regards institutions for private patients, in many of them not only have fabric and equipment been brought up to date, but the treatment aspect is paramount and the element of detention is receding as is illustrated by the increase of voluntary admissions. Up to the time of the 1890 Act and even afterwards, there was great activity in building rate-supported institutions, some of which reached an immense size. Of later years there has been a return to smaller hospitals, and this is desirable on many grounds. Those of you who can look back on the asylums of 35 years ago will probably agree with me that the most striking change on entering a large institution to-day is the comparative absence of noise in and about the buildings. When I first became familiar with mental hospitals I was much impressed by the restless excitement that prevailed, the shouting, singing, and constant chatter of conversation. All that has changed and the quietude even where large numbers are resident is in itself a testimonial to the way in which the gradual hospitalisation of our mental institutions is taking place. I believe that one of the chief factors responsible for this change from noise to peace has been the withdrawal of beer from the diets of our patients. Also the steady diminution of acute and chronic alcoholic insanities from the wards of our institutions during the term of my practice has been remarkable. Alcohol was an exciting or predisposing factor in at least 23 per cent of cases admitted to asylums round about 1890. This figure had fallen to less than half in 1920.

I can recall many improvements in the administration of large hospitals. All of us have gladly seen the last of the old term "Pauper Lunatic Asylum." Rate-aided patients are better clothed, and their dresses and suits are less like uniforms than they were. Provision for occupation, both in and out of doors is more generous, and work is often rewarded with some local currency with which patients may make simple purchases in a shop or store provided for the purpose. Contact with the outer world is maintained more completely, by newspapers, wireless, and an increasing system of leave and parole. Cases are separated into categories as far as that is possible, and few institutions are now without a reception ward or wards for each sex, even if a separate building is not available for the recent cases.

Another necessary change for the better in the care aspect of our patients has been the improvement in the dietary scales. There is, in my opinion, a close connexion between diet and the occurrence of those preventable maladies, tuberculosis and dysentery, which were endemic in many large institutions. The high incidence of tuberculosis caused great concern between 1890 and 1900, and one often heard that all mental hospitals should build adequate open-air wards for the isolation and treatment of cases which were bound to occur. Much argument was forthcoming concerning the statistics of tuberculosis cases occurring in mental hospitals as compared with its appearance in the general population. Some authorities maintained that it was ten times as high in asylums as in the sane community. While this figure may be too severe, there is no doubt that tuberculosis was very prevalent in institutions for the care of the insane. Deaths from tuberculosis, indeed, in mental hospitals rose to alarming proportions during the war, when diets were necessarily cut down to a minimum. What used to be known as "asylum dysentery" is a phenomenon of great interest and its causation and proper treatment has now been accurately determined. It is noteworthy that deaths from tuberculosis or dysentery are very rare in registered hospitals. In licensed houses, where the meals closely resemble those enjoyed by the middle and upper classes, cases of either disease are practically unknown. It would seem as if these two scourges tend to decrease as the standard of living improves. Much attention used to be paid to caloric values, and it may well be that some of the scales of diet have lacked those elements known as vitamins which we have learned are essential to a state of good health, and consequently a high resistance. Dietary scales, it is satisfactory to record, have been much improved of late, and it will be interesting and instructive to observe the effects on the incidence of dysentery and tuberculosis, as well as on the recovery rate.

Coincident with the growth of the hospital idea we find the slowly developing practice of employing female nurses for male patients. This has had excellent results, but is still in a somewhat experimental stage, and I do not believe that the good male nurse will ever entirely disappear. The progress in the standard of nursing in mental hospitals can best be described as amazing. The Royal Medico-Psychological Association must be given much of the credit for this work. The syllabus of training and examinations for the proficiency certificate in mental nursing was commenced 35 years ago. The official handbook has grown in size with successive editions, and the seventh and latest, published in 1923, is a most informative and complete guide to nurses, and might well be studied by practitioners and students. General as well as special training is being insisted upon, and the formation of a State Register on which mental nurses may be included is a step in the right direction. Rates of pay and hours of work have been improved, until there is a danger of professional nurses losing sight of the nature of their calling, and regarding their hours of labour as so much routine, which true nursing can never be. I believe that the arduous training now necessary for nurses to qualify will remove entirely such tendencies, and that interest in the work will be essential if a nurse is to pass the necessary examinations.

There is one excellent movement which I have seen developing, and which is likely to become more general. I refer to occupational therapy. It is true that patients have been employed in workshops, laundries, and farms, where they have been largely engaged in routine work, often of a lowly nature. But occupational therapy is meant to inform, to recreate, and re-educate. We owe a good deal to American practice for this aspect of treatment. Not only is occupation of great value in convalescent states, but terminal dementia may be held off for many years if some regular occupational interest be provided. Instructors are necessary, and a great variety of work can be made available. At the Bloomingdale Hospital, New York State, 80 per cent of the patients take up some daily task during their residence. Some American hospitals have adopted physical training classes, conducted by a resident instructor who may have a gymnasium at his or her disposal. Pioneer work of this kind is now being carried out in this country, and I hope the system will take its place in the equipment of all our large hospitals.

Progress in treatment must ultimately result from research and advances that are made in other branches of science. The whole of the past 35 years has been marked by a slow but increasing equipment in laboratories and devoted laboratory workers. In this psychiatry owes a debt to the London County Council, who established the central laboratory at Claybury 35 years ago, now moved to Denmark Hill. While London may rightly be considered the centre of psychiatric research, much activity has been shown by workers scattered throughout Britain. I recall the labours of Bevan Lewis at Wakefield, the for research, generous contributions to the funds of mental institutions, and, above all, the trust that has been happily given to medical men in every other branch of practice

And now nothing remains for me but to thank you for your kind attention To those of you who are about to take up the difficult and sombre study of insanity I would say that the future is bright with hope. In spite of all that has been done, wide tracts of virgin soil still lie before us Let our interest direct our work, there is a place for all, be it at the bedside or in the laboratory We shall need patience and tolerance; and if we serve faithfully the needs of our patients, continued progress in psychiatry will be assured

A CASE OF
ENCEPHALITIS LETHARGICA OF SEVERE TYPE.

TREATED SUCCESSFULLY BY INJECTIONS OF ELECTRO-COLLOIDAL GOLD AND SILVER

By ARTHUR W FULLER, M D Edin

As a good deal of attention is being given at the present time to encephalitis lethargica and its treatment, especially by medical officers of health, the following clinical report may be of interest

The patient, a lady aged 68, after complaining of recurring pain in the right temporal region for a few weeks, had an attack of vertigo in the street, she was brought home and relapsed speedily into a condition of stupor from which, however, she could be aroused Sir William Willcox was called in consultation, and the diagnosis of encephalitis lethargica was made, with a grave prognosis The cerebrospinal fluid, which was examined by Dr A B Porteous, was found to be normal, except for a very slight lymphocytosis, there being no excess of globulin. Cultures were sterile and no T B present.

Symptoms and Course of the Disease

The face was expressionless and mask-like The mental condition was stuporose alternating with delirium, especially at night She spoke with great difficulty and hardly above a whisper. There was spasmodic twitching of the face and muscles of the neck, and she complained of pain on the right side of the face and temporal region, also of frontal headache The antra and nasal sinuses were examined by Sir James Dundas-Grant and found normal The urine showed a trace of sugar All the reflexes were present There was no diplopia, but the ocular movements were performed with difficulty, especially the upward and downward, the horizontal movements being much less impaired, bilateral ptosis was also present There was great dryness of the throat and deglutition was very slow The patient lay almost immobile, except for involuntary movements of the right arm and hand resembling those of paralysis agitans

Third day The general asthenia was more marked, the stupor increased, and incontinence of urine and fæces supervened The temperature rose to 102° F and then dropped in the evening to 100°, with a morning drop to 99°, probably as the result of the fever mixture which was given The pulse-rate was about 90 per minute and became very small and weak at times, necessitating the administration of small doses of brandy. The left arm was now completely paralysed and she could only move the legs a little and with difficulty

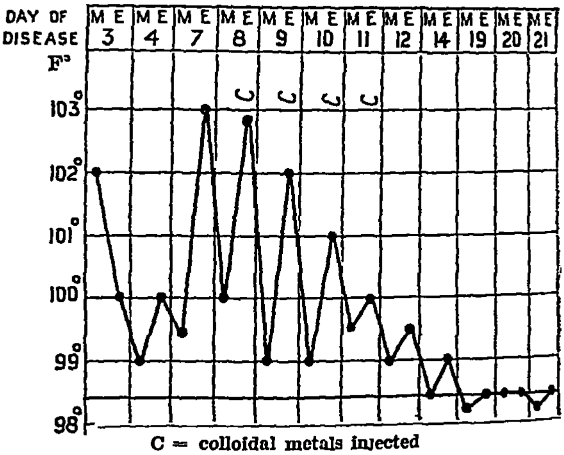
Fifth day There was considerable erythema on the buttocks and round the hip-joint

Sixth day There were increased spasmodic twitchings of the face, eyelids, and right hand and leg, great stiffness of the neck muscles, increased difficulty in articulation and swallowing, and deep stupor, from which it was extremely hard to rouse the patient

Seventh day The temperature rose to 103° It was now almost impossible to rouse the patient, and feeding by the mouth had become quite impossible The respirations, which had been about 28, suddenly rose to 52 on the eighth day

There appeared little chance of recovery, but, knowing that electro-colloidal metals, particularly colloids of silver and a combination of silver and gold, had been employed successfully in the treatment of general infections, I decided to give an intravenous injection of 0 05 per cent suspension of gold-silver colloid The first result was a return to consciousness within an hour, the temperature dropped one degree, the respirations became 36 per minute instead of 52, and the pulse, which had been 140, fell to 120

Next day the temperature rose again to 102° at 10 P.M. when another intravenous injection was given. After this the temperature commenced to fall steadily, and at 2 P.M. the following day it was 99° There was a marked improvement both in swallowing and in articulation, and the patient was much more easily aroused The maximum temperature at night was now only 101°. Two more injections were given on this and the following evening, intramuscularly They were then suspended altogether for a few days, but the improvement persisted



C = colloidal metals injected

On the tenth day the mental condition was markedly better, but there was still incontinence of urine and fæces The maximum evening temperature was 100°

On the twelfth day there was some powers of movement in the left arm and hand.

On the fourteenth day her speech was almost normal, albeit a little slow, and she moved her arms and legs more readily, but there was still some nocturnal delirium. The maximum temperature, which had shown a slight improvement each day, was now 99° the ophthalmoplegia became less marked, the fibrillary muscular movements and twitching of the face and neck muscles subsided, and the power of voluntary movement gradually returned

On the sixteenth day the silver-gold colloidal injections were resumed daily for four days, as the mental condition was not satisfactory and was not improving pari passu with the other symptoms, for she still had some nocturnal delirium and illusions The result was marked, for she began to take an interest in her surroundings, to converse intelligently, the delirium at night was less, and the incontinence ceased a few days later The temperature was now normal at night

At the end of four weeks the patient could sit up and eat simple ordinary diet There was still asthenia, but she was gaining strength steadily At the end of five weeks she was able to walk about her room and her mental condition was nearly normal, her memory being fairly good

At the end of the sixth week, beyond general debility, there were no abnormal symptoms except that sometimes she complained of sleeplessness and some stiffness of the muscles of the neck

It is now five *months* since the acute symptoms subsided; there are no abnormal physical or mental signs, and she is resuming her usual social life

Remarks on Treatment

Besides the gold-silver injections, which acted like a specific in this case, the great desideratum is good nursing, which happily was available The stuporose, almost comatose, condition of the patient, the complete incontinence and general utter helplessness, are a heavy tax both on the skill and patience of the nurses The subsidiary treatments included the use of an ice-bag and various analgesics for the pains in the head, which at times were very severe, antiseptic swabbing of the mouth and the administration, during sleepless and restless periods, of mild hypnotics But beyond all these in importance is the question of nutrition In this case rectal feeding never had to be resorted to. Stimulants must be given occasionally, and both brandy and hypodermic injections of liq strychninæ ♏v were administered, when there were signs of collapse, which were not infrequent Milk, Brand's meat juice, malted milk, coffee, Allenbury's food, Eatan, jellies, &c, were all found useful during the acute stage

With regard to the colloids, their action is that of a protein stimulant, but, unlike many other stimulants, there appears to be no subsequent depression if given in small enough doses There is a reaction of course, but it is a reaction against the disease, similar to that produced by a vaccine, and is not a severe one Their advantage over vaccines in cases where the specific organism cannot be isolated lies in the fact that they are always ready to hand and can be given at once either as a substitute for, or as a preliminary to, vaccine therapy, and with as good if not better results It would be interesting to know if the gold-silver colloids have been used before in this country in epidemic encephalitis for the most gratifying results of their employment in this case has been that the changed mental condition and various types of paralysis so frequently observed as sequelæ have not occurred

Among other treatments recommended for this disease are intramuscular injections of 4 c cm of a 25 per cent solution of magnesium sulphate (Edwin Matthew, THE LANCET, 1924, i., 1157), intravenous injections of sod salicylate 1–30 solution have been used with reported good results by Rathery, Gournay, Courcoux, and Maignant A vaccine has been made from the fixed virus of encephalitis lethargica and improvement from its use has been reported, but the evidence is inconclusive

The bacteriology of the disease is at present unsatisfactory, but Loewe, Strauss and Thelhimer have grown an organism resembling that of Flexner in poliomyelitis

The infectivity is very low and contacts rarely appear to suffer

The clinical picture is that of a general infection, and the organism is probably a filtering bacillus producing a virus, which has a selective action on the brain and spinal cord by way of the cerebrospinal fluid, the symptoms varying according to the damage which may result whether in the meninges, cerebral hemispheres, basal ganglia, pyramidal tracts, &c The incontinence which is so constant a symptom is mainly due to the lethargy and general stuporose condition

The after-treatment is the treatment of convalescence, with special reference to abundance of rest and sleep and rigid exclusion of all excitement, the avoidance of strong tonics, and the recognition that the time may be considerable before complete restoration takes place

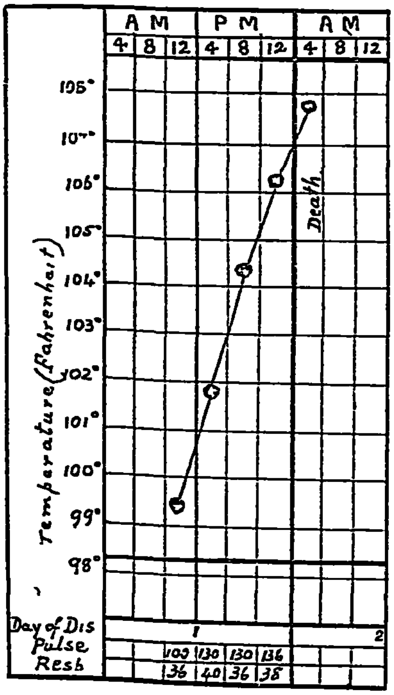
A NOTE ON TWO CASES OF CENTRAL PONTINE HÆMORRHAGE

By A MUIR CRAWFORD, M D, F R F P S GLASG,
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, GLASGOW

A STUDY of the symptomatology of hæmorrhage into the pons demands on the part of the clinician, a clear conception of certain anatomical and physiological facts concerning this most important part of the brain Without entering into an elaborate discussion on the anatomy and physiology of the pons, it will be sufficient in this short article to summarise briefly the essential points to be borne in mind in endeavouring to comprehend the symptomatology of pontine hæmorrhage (1) The pons varolii lies in close proximity to the medulla crura cerebri, and cerebellum (2) It contains motor and sensory tracts coming from and going to the brain, the former passing down through the anterior (ventral) part and the latter passing upwards through the deeper parts (3) The nuclei of the fifth, sixth, and seventh nerves are placed near the floor of the fourth ventricle, while immediately in front of the pons lies the superficial origin of the third nerve (4) The basilar artery runs along the grooved anterior surface and gives off transverse branches which supply the pons

It will be obvious, therefore, that in such a complicated structure the symptomatology of hæmorrhagic lesions must be varied and complex according to the part of the pons involved and the extent of the lesion Thus in small hæmorrhages there may be no loss of consciousness, while in large hæmorrhages convulsions and early loss of consciousness are notable features, to which may be added the characteristic symptoms of crossed paralysis, conjugate deviation of the eyes and head to the side away from the destructive lesion, contracted pupils and hyperpyrexia In small unilateral lesions the paralytic phenomena associated with the cranial nerves will vary according to the site of the lesion Large hæmorrhages are usually central and are characterised by sudden loss of consciousness, bilateral paralysis, contracted pupils and hyperpyrexia The following two cases are examples of large central hæmorrhage in which these symptoms were well marked Both cases showed extreme hyperpyrexia immediately before death

CHART 1

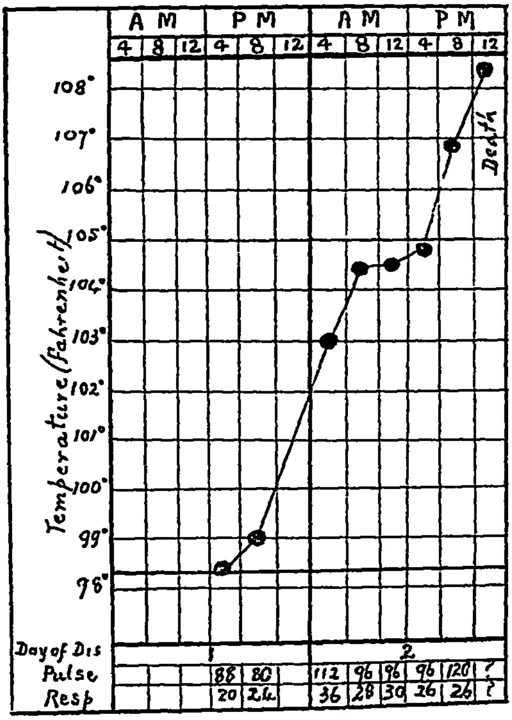


CASE 1 —Male, aged 31 years Admitted to hospital in the evening of Dec 21st, 1922, with the history of having suddenly been taken ill while attending a social function The attack began with an epileptiform convulsion, which was preceded by a feeling of nausea and followed by coma There was no history of previous epilepsy and no history of kidney trouble On admission the patient was deeply unconscious The pupils were moderately contracted and fixed, later on they became pin-point The conjunctival reflex was absent The face was of a pale cyanotic hue and the breathing stertorous He vomited a considerable amount of mucus mixed with some food material There was extreme rigidity all over, especially on the right side the smallest stimulus elicited clonic spasm of all four extremities The knee-jerks were greatly exaggerated with double ankle-clonus and positive Babinski on both sides, the arm jerks were increased On the following morning he was deeply comatose, the reflexes generally were abolished, and the pupils pin-point and immobile The urine contained a trace of albumin, but no blood, and tube casts were not found Systolic blood pressure was 190 mm. The patient died about 27 hours after the onset of the illness The temperature having steadily risen, reached 107 8° F just before death (Chart 1)

The autopsy showed a large central hæmorrhage into the pons, bursting through on its inferior surface on the right side A small amount of blood had effused into the basal cisternæ The kidneys showed the changes of chronic interstitial nephritis with some cloudy swelling The heart showed enlargement of the left ventricle, marked recent atheroma of the aorta, and thickening of the valves

Case 2 —Female, aged 51 years This patient became suddenly ill about midday on Jan 4th, 1925, and was admitted to hospital an hour later It was ascertained that she had been out of sorts for two months with "nervous trouble" The present illness began with vomiting, inability to stand or speak, and the early onset of unconsciousness On admission the patient was comatose There was rigidity of the arms and legs and the pupils were contracted and equal An hour later the right arm was becoming flaccid and there were signs of right-sided facial palsy The left arm and both lower limbs were still rigid, with much exaggerated knee-jerks and positive Babinski The head and eyes were turned to the left Next day the head was kept to the right side The heart showed signs of hypertrophy Systolic blood pressure 180 mm The urine contained a moderate amount of albumin, but casts could not be found Death occurred 35 hours after the onset of the illness and was preceded by a temperature of 108 1° F (Chart 2)

Chart 2



The autopsy showed extensive hæmorrhage involving the pons about its centre The hæmorrhage had burst into the fourth ventricle and blood was present in the whole ventricular system The cerebral arteries were very brittle and showed signs of atheroma The kidneys showed slight interstitial changes with a notable sclerosis of the renal vessels There was considerable hypertrophy of the heart, especially of the left ventricle, the aorta showed patches of atheroma

For permission to publish notes on these two cases I am indebted to Dr J B Mackenzie Anderson, into whose wards the patients were admitted

TUBERCULOSIS VERRUCOSA TREATED BY ULTRA-VIOLET RADIATION

AND ASSOCIATED WITH UNSUSPECTED TRICHINOSIS

By M WEINBREN, M R C S Eng , B Sc S Africa, D M R E Camb ,
MEDICAL OFFICER IN CHARGE OF ULTRA VIOLET DEPARTMENT, THE QUEEN'S HOSPITAL, SIDCUP , HON ACTINO THERAPIST, MOUNT VERNON HOSPITAL ,

AND

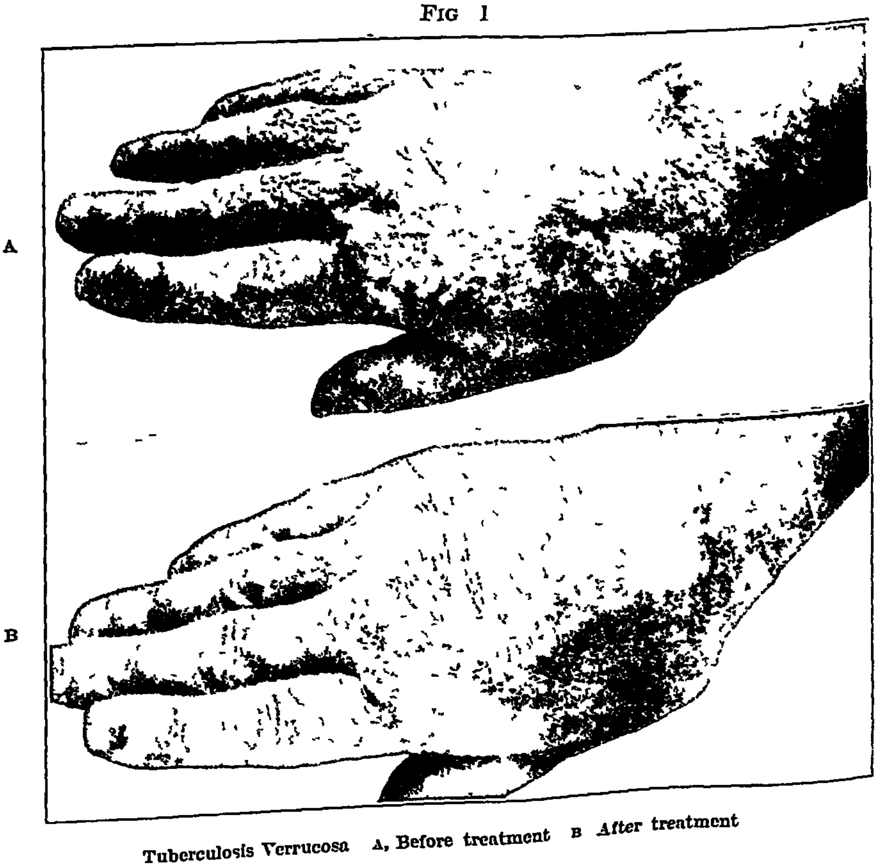
H K GRAHAM-HODGSON, M B , B S Durh D M R E Camb ,
RADIOLOGIST, KING'S COLLEGE HOSPITAL , MEDICAL OFFICER IN CHARGE OF X RAY DEPARTMENT, THE QUEEN'S HOSPITAL, SIDCUP

There are a number of interesting facts in connexion with this case which seem to justify its publication

Pensioner D , aged 53, was admitted to the Queens Hospital complaining of chest trouble

History —He served with the colours in Africa from 1891 to 1902, during which time he does not appear to have suffered from any serious illness In 1914 he re enlisted but was discharged the same year In 1915 he re enlisted and was sent to France, but he was sent home the same year and discharged on account of ulceration of the rectum In 1917 he again re-enlisted and was again discharged for ulceration of rectum and old fistula Not disheartened by his frequent discharges he again enlisted in 1919, this time in the Exhumation Corps While in France he contracted chest trouble (chronic bronchitis) He also states that while exhuming a body he scratched his right hand , within a fortnight the skin became swollen and several warts appeared at the site of the scratch These were cauterised at a dressing station, but the warts continued to spread up the arm and he was discharged owing to his chest condition and the condition of the arm His record card shows that the diagnosis verruca necrogenica was made in 1921 and that he was then being treated with liq acid nitrat of mercury

Fig 1

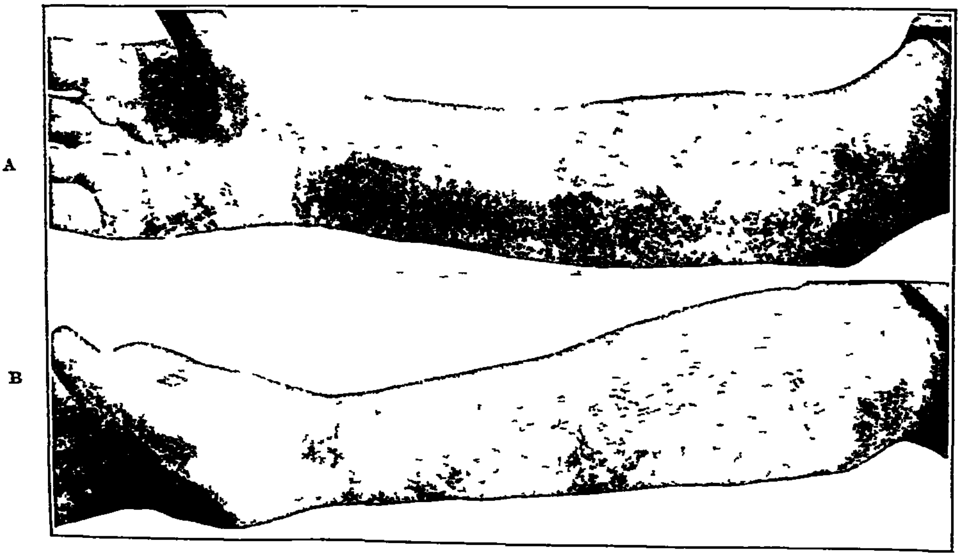


Tuberculosis Verrucosa A, Before treatment B After treatment

The patient's story is that the arm condition has been continually treated without benefit since his discharge in 1919

On admission the physical signs and a radiogram of his chest showed that he was suffering from chronic pulmonary tuberculosis Although frequent examination of his sputum was negative, when inoculated into a guinea-pig a positive result was obtained The complement-fixation test for tubercle was also strongly positive, the Wassermann reaction negative

FIG 2



A Before treatment B, After treatment

From his history and the record of his physical signs it is very probable that even in 1919 the chest trouble was pulmonary tuberculosis, the diagnosis not being made owing to chronic bronchitis masking the condition. The skin of the dorsal aspect of the fingers and right hand, and of the forearm, on its ventral aspect, was indurated and in places warty and ulcerated There was also a patch on the medial aspect of the arm (Figs 1 (A) and 2 (A)) Microscopically no particular organism was discovered, cultures were negative and a guinea-pig inoculation with pus from the ulcer proved negative also In spite of these findings the condition was regarded as tuberculosis verrucosa, the source of infection being either the patient's sputum or the body he was exhuming at the time he scratched his hand Dr H G Semon, dermatologist to the Ministry of Pensions, to whom the case was sent for an opinion, concurred with this diagnosis

Treatment —The arm was cleaned up with hot fomentations and ultra-violet exposures were started, local treatment was given with a mercury-vapour lamp and general radiation to the whole body with a Westminster lamp (30 amps white flame) The general radiation dose was started with 5 minutes at 4 feet the patient being placed between two arcs each 4 feet from the body This dose was increased to 20 minutes daily The danger of hæmoptysis in the treatment of pulmonary tuberculosis with ultra-violet radiation has been stressed in the literature dealing with the subject Admittedly great caution is called for, but this patient's chest condition was not regarded as a contra indication to general ultra violet radiation

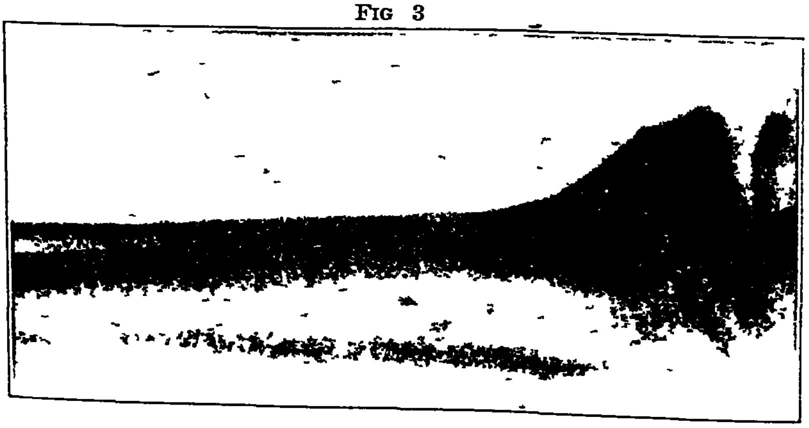
The local treatment was at first given with the Hanovia Alpine Sun lamp, 4 areas being treated daily and the dose to each area being increased from 4 minutes at 18 inches to 10 minutes at 9 inches The areas showing more extensive and dense induration were treated with the Kromayer lamp using the 5 mm uviol blue water-cooled filter the starting dose being 5 minutes and increasing to 15 minutes in contact This filter cuts off rays shorter than about 000 Å (A 3-minute exposure under these conditions on healthy skin will give between a second and third degree erythema resulting in pigmentation which will persist for a number of months, in some cases six months or longer)

Each area received an exposure every three to four days The condition rapidly improved (Figs 1 (B) and 2 (B)), and according to the patient it is now better than it has been during the last six years The treatment could have been pushed more rapidly—that is, more areas could have been treated each day—but for the heavy demand on the Kromayer lamp

The hand was X rayed for underlying disease of the bones, the patient giving a history of a fractured thumb There was no tuberculous disease evident, but unusual oval-shaped calcareous nodules were found in the muscles, suggesting trichinosis The lower limbs, consequently, were also radiographed and similar nodules were shown (Fig 3)

The patient has been questioned in the hope of discovering the probable date of infection with the *Trichinella spiralis* He denies ever having eaten raw pork, but the infection may have come from sausages[1] There is no history of any of the symptoms usually associated with the condition[2]—intense catarrhal inflammation in the intestinal canal, and symptoms which may suggest cholera or dysentery and may be associated with hyperpyrexia; rheumatic muscular pains when the embryos begin to wander from the intestinal mucosa via the lymph channels and blood stream to the striated muscles—nor does he complain of any muscular pains at present From the amount of calcareous infiltration, the lack of eosinophilia (the eosinophil count is only 1 per cent), and the absence of cysts in the stools it would appear that this is an old-standing case The encysted trichinæ may remain alive as long as 20 years before they become calcified and the embryos die[3] It is owing

FIG 3



Radiograph of leg showing parasites.

to this unusual absence of all symptoms that the condition was only diagnosed by radiography Without dissecting out one of the cysts it is not possible to be absolutely certain of the diagnosis, but the radiographic appearance suggests the presence of some calcified parasite, and, as far as we know, cannot be accounted for otherwise

A NOTE ON THE TREATMENT OF VARICOSE VEINS BY INJECTION

BASED ON FOURTEEN MONTHS' EXPERIENCE

BY SIR SIDNEY ALEXANDER, M D LOND

THIS method of treating varicose veins was devised by Prof Sicard and Prof J Paraf, of Paris, largely as the result of their observations during the war, when they noticed that thickening and obliteration of the veins occurred in the course of treatment by the intravenous injection of certain novo-arsenical products I am indebted to Prof Paraf for his personal explanation and demonstration of the methods adopted later on for the express purpose of procuring this " phlebo-sclerosant " result

Investigation showed that this obliteration of the veins is due to an excess of soda in the solution, and did not occur when absolutely neutral solutions were used This observation led to the use of carbonate of soda solutions in the hope that they would produce the desired effect and yet not be toxic to the patient After successfully using a solution of carbonate of soda, Paraf and Sicard found that, although it was efficient as a sclerosing agent, it was too caustic to the perivenal and subcutaneous tissues, in view of the possibility of oozing from the veins or an error of needling They therefore tried other substances, including chloride of calcium, and hyposulphite of soda, finally settling on salicylate of soda in solutions of 20 per cent , 30 per cent and 40 per cent The salicylate was found effective in producing obliteration of the vein , it was not caustic to surrounding tissues, nor toxic to the patient (Indeed, as I have found, it is actually beneficial where arthritis and other " rheumatic " troubles are present, as is often the case) Even with salicylate, in poorly nourished tissues, should an oozing occur, there may very occasionally arise a limited " scar " , but this slowly heals without incident and without any tendency to spread The veins are cured in the meanwhile

In cases where the varicose veins are accompanied by varicose ulcers—especially where there is any reason to suspect syphilis—a 1 per cent solution of biniodide of mercury and iodide and chloride of soda in distilled water may be used This is quite effective, but has the disadvantage of being toxic, and can therefore only be administered in small doses The consequence is, of course, that the treatment is very much prolonged ; if pushed it may produce the usual reaction in the gums and elsewhere. Where varicose ulcers exist, I combine the injection method with the administration of parathyroid and calcium

The intravenous injection of salts of quinine has been tried by Genevrier, but Sicard and Paraf had occasion to use these largely during and after the war in the treatment of malarial cases and found these salts much too caustic for use in the treatment of varicose veins

Having practised, since May, 1925, the method perfected by Sicard and Paraf, I have effected the cure of some 100 cases of varicose veins, notes of which I have made These cases include several which had previously been subjected to excision of the veins—even twice—and in which the condition had recurred They also include many in which the patient, on account of the extent and distribution of the varicose condition, had been told that it was inadvisable to have the veins excised.

One such was a remarkable case in which there was varicosity of the saphena magna, saphena parva, and accessory saphena of both legs, the superficial circumflex iliac and the superficial epigastric up to the diaphragm, the vena dorsalis penis, and the venæ pudendæ externæ of both sides There was some œdema of the legs. Having satisfied myself that there was no obstruction of the deep veins, I started the treatment and had the satisfaction of curing all the veins ; the œdema of the legs completely disappeared During the whole time of treatment the patient, who is a gardener, kept at work , and indeed he worked with more ease and less fatigue during the progress of the cure than before

It is advisable to start the treatment with an injection of the 20 per cent solution in order to test the reaction of the patient Sometimes slight faintness is noticed, but this quickly passes off and seldom occurs after the first injection , it is purely emotional in origin. No general reaction occurs and there is no subsequent febrile disturbance On injection of the solution into the vein there is often a quite sudden constriction of the vein for a few inches, and in a large vein the convexity may become concave, " like a gutter," sometimes the skin in the vicinity of the injection shows " goose skin " over a small area The injection may be followed by some cramp in the foot and calf, but this is always supportable and lasts only three or four minutes or less

Of later effects there is really only one—and this is local It is what Sicard and Paraf call " endo-veinite," but as there is no febrile disturbance I should prefer not to use a term ending in " itis," which denotes inflammation Instead the condition may be described as chemosis of the intima which suggests acute congestion of the vein This may be sufficient to cause the opposing walls of the vein to meet and adhere and so obliterate the lumen A solution of salicylate of soda does not, of course, cause coagulation—indeed, in vitro it restrains clotting , but it has been shown by examination of portions of veins removed after treatment by this method that a thrombus, which forms firm and intimate adhesions to the walls of the vein, may form and become organised into a fibrous cord No movement of this organising thrombus has been ever been recorded, although the method has been practised since 1916, and I think we may be satisfied that no embolism ever occurs except in phlebitis with septicæmia with which this treatment is, of course, not associated

A further effect, coming on three or four days after the injection, is a slight reddening of the skin along the course of the vein treated, with some swelling and slight tenderness to the touch These are good signs and show that the treatment is succeeding Should the patient wish to do something for this tenderness, a simple warm fomentation affords relief to the slight pain which occurs

The first injection is followed up a week later by injecting the 30 per cent solution, and, later on, if necessary, 40 per cent solution

It is singular that so little attention seems to have been paid in England to the literature of this interesting and gratifying method, for accounts have been published in many journals[1] Of about a hundred cases that I have cured, only one has given me any real anxiety This was a case in which, three weeks after the saphena magna from foot to fossa ovalis was cured, the patient developed fever (102 2°) and rigors

The history of the case showed that this patient had since about 1910 been subject to occasional shivering fits lasting two or three days, the cause of which had remained undiagnosed because he did not consult a doctor A bacteriological examination showed *B coli* invasion, and his own doctor assures me that he does not consider the febrile attack to have been caused by the injections

Scarring that sometimes occurs at the point of injection heals slowly but certainly It can be altogether avoided by strict attention to every point of the technique I am often asked if recurrences occur So far I have not seen any, but Sicard and Paraf with their longer experience say that "after two or three years a small number of patients return asking for more injections, as another vein—at a distance from that previously treated—has appeared," the facility with which these can also be cured being realised by the patient In conclusion, I may confidently say that in this method of treatment we have a means of curing the patient without laying him up or interfering with his business engagements or usual habits It is almost painless, and even those who complain of some pain are quite anxious towards the end of the treatment that no vein should be left untouched With due attention to all the proper technique it is quite innocuous and most gratifying to the patient

I again acknowledge my indebtedness to Prof Paraf for initiating me into his technique and allowing me to make use of his investigations and experience

Welbeck street, W

Medical Societies.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION

THE annual meeting of this Association took place at the British Medical Association House, Tavistock-square, London, on July 13th to 16th, under the new President, Lieut-Colonel J R LORD At the conclusion of the business meeting, at which tributes were paid to the late Sir Frederick Mott, formerly President of the Association,

Dr G A. AUDEN read a paper on the

Madness of Ajax as conceived by Sophocles

Dr Auden said that in his delineation Sophocles probably had in mind an attack of malaria, and the psychological insight shown argued an actual experience of insanity The poet was specially associated with the cult of hero-physician The picture drawn by Sophocles was a masterly presentation of delusional insanity, and the accuracy of it had been praised by many writers —The PRESIDENT said that Sophocles had appeared to have invested Ajax with attributes which were strongly marked in his own make-up —namely, jealousy and rivalry.

Dr T H HISLOP, Prof G M ROBERTSON, and Dr H J NORMAN also spoke

In the afternoon Colonel LORD delivered his Presidential Address on the

Clinical Study of Mental Disorders

He first referred to the fact that the Association had been granted a Royal Charter which he regarded as a recognition of the work which it had accomplished In the domain of knowledge he said, the modern man's criterion was utility rather than culture The Association was concerned with psychology in its broadest sense, it was now a living science, and the various schools of psychology were being judged according to the way in which they responded to the tests now imposed He urged the re-establishment of the Research Committee, which should include in its functions that of the definition of psychological terms and the collection and classification of clinical data for the aid of research work particularly, but also for the purposes of psychiatry generally. He would also like to see the needs of junior psychiatrists catered for in the shape of meetings for studying clinical psychiatry. He indicated several ways in which he considered the machinery of the Association could be bettered, and he also had much to say in favour of facilitating more research in the subject under conditions of team-work There was no sharp division between clinical psychiatry, clinical psychology, and clinical neurology, indeed, he regarded clinical psychology as the link between the other two.

The President proceeded to deal in some detail with the psycho-analytical conceptions of Freud, and the modifications of them held by Jung and Adler, remarking that the clinical psychiatrist nowadays was tending to view his cases more from the point of view of instincts, impulses, motives and wishes, and less from that of reason, judgment, belief, ideas, sensation, and hallucination. He sought to investigate the mind of the patient from its infancy in order to discover the cause of the condition found The President praised the work of Mott in psycho-pathology; it was true that bodily processes were a sounding-board for mental processes, and vice versa As to the word "recovery" as applied to mental cases, the President declared that what constituted recovery was indefinable, seeing that it depended on the normal mental make-up of the patient and his environment, which differed in each individual case Freud's definition of cure was the restoration of productive ability and the capacity for enjoyment To establish and further develop team-work in public mental hospitals would mean a reorganisation of the work of the medical staff, and the addition to it of specialists and experts in the various departments of medicine As little as possible of the time of the skilled psychiatrist should be spent on cases of chronic insanity; nurses and other lay officers were now so skilled that they would now take on more responsible work than formerly, and much of the work in connexion with chronic cases could be done by medical men who had not been specially trained as psychiatrists He set out a carefully elaborated plan of medical organisation for mental hospitals, contending that it afforded a fine opportunity for team-work

In conclusion, the President said he hoped the time would soon arrive when all mental institutions would be equal before the law. There was a wealth of psychiatric practice in general medicine, and it was not right to regard the former as outside the realm of the latter In general practice there was great need for the practice of psychiatry, especially in regard to child life, the training of adolescents, and the promotion of better industrial efficiency of adults

On the motion of Dr C HUBERT BOND, seconded by Prof ROBERTSON, a cordial vote of thanks to the President for his address was carried by acclamation

Encephalitis Lethargica

Wednesday morning was devoted to a consideration of this subject, when papers were read by Dr R L MACKENZIE WALLIS and Dr C FARRAN-RIDGE

Dr Mackenzie Wallis's paper dealt with the subject particularly from the standpoint of hepatic insufficiency, and was the account of a research which was partly experimental and partly clinical In the disease as transmitted to experimental animals there was, during the acute stages, a rapid increase in the lipase content of the blood—especially so when immunity had developed There was a striking association of mononuclear activity with the raised lipase content of the blood When an intensive inoculation of the vaccinia virus had been made into the skin of the rabbit there was a rapid rise in the cholesterol content of the blood—namely, from the normal 0 07 to 0 16 per cent in eight days Encephalitis lethargica produced a profound effect on the kidneys, liver, and spleen of the animals, the blood also showing evidence of hepatic inefficiency Among 40 human cases of the disease, 25 gave evidence of hepatic derangement, most of the acute cases also showed a raised lipase content and a higher cholesterol content than the normal

Dr Farran-Ridge's paper dealt with the clinical manifestations of the disease as he had met with them in practice He said it was not surprising to see, in cases of encephalitis lethargica, symptoms of various psychoses reproduced, seeing that the epidemic disease might attack any part of the brain Especially did it mimic the manifestations of dementia præcox

The Educational Adaptation of the Child

On Wednesday afternoon members accepted the invitation of Sir George Hume, the chairman of the London County Council, and his colleagues to meet at the County Hall to hear and discuss a paper by one of the medical officers, Dr F C Shrubsall, on Educational Adaptation of the Individual Child It consisted of a statement of the mechanisms and organisation set up by the L C C to get the best out of every child in the immense area covered by it, and to provide every provision and facility for backward and defective children The attention necessary to be given to the case of the parents was also stressed, while the children's physique was well looked after

The whole of Thursday morning was taken up with a debate on

Psycho-Analysis and its Development.

The opening paper was read by Dr W A. **POTTS** He said there was a mass of past experiences in the mind which could not readily be remembered, and processes went on in it which eluded the observation of the person concerned The modern psychologist said that the hidden mental processes were in the unconscious or the subconscious mind—i e, the inaccessible Freud, when dealing with neurotic and mental conditions, noted that some patients experienced relief and showed improvement when they were encouraged to talk frankly about their anxieties and difficulties, and he proceeded to work out a method of exploring the unconscious mind, which he named psycho-analysis The method showed to Freud the real motives of unusual and irregular conduct, and he became convinced that the unconscious mind consisted largely of unfortunate experiences in early life, of primitive instincts and desires, many of them sexual in character. Abnormal conduct was often a result of conflict between the conscious and the unconscious, because the demands of the moral code set up resulted in a repression of primitive desires Freud was convinced that not only a person's dreams, but the events of his whole mental life were due to definite causes, and were not the results of chance Sex was assigned the first place by this authority among these instincts, but with Freud sex has a wider significance than physical gratification, including such attributes as parental love Jung accepted Freud's dicta with modifications and attached a great deal of importance to the power of present ideas Dr Potts explained that psycho-analysis was a reductive process, working down gradually to the pleasure principle operative in early childhood Dr Potts said it was most desirable that those who undertook to practise psycho-analysis should themselves have been subjected to the process by an expert Neither those of the Freud nor the Jung school subjected to psycho-analysis all who came to them The method was most suitable for cases of so-called neuroses and psycho-neuroses In some cases of incipient mental disorder, analysis would precipitate an acute condition He insisted that the physical condition of patients should always be investigated and treated

Dr W **BROWN** (Oxford) expressed his general agreement with Dr Potts's paper He had himself been analysed, and he considered that the process as practised by the several schools was the same in quality But he contended that it would be difficult to find anybody who had been completely analysed He gave a brief sketch of Freud's most recent work on the libido theory

Dr A **WOHLGEMUTH** held the view that suggestion on the part of the analyst had much to do with the results claimed

Dr M. **HAMBLIN SMITH** supported the claims of psycho-analysis, and gave the history of the attitude of the profession on these matters Many senior doctors entertained quite a strong bias against psychology Freud's system dealt with the normal as well as with the manifestations of the disordered mind Many sound and permanent results had been brought about directly by the practice of psycho analysis, and much would be done in the prevention of mental troubles by the application of the knowledge now available

Dr. E **MAPOTHER** said that what really concerned psychologists were the results of treatment, and the question which required to be answered was whether results were obtainable by the special methods of psycho-analysis which could not be attained otherwise After 20 years he was still in doubt The essence of the matter was free association and the attempt to trace anomalies to deviations of the infantile sexuality by that method Yet truly free association was scarcely ever attainable In practice the intervention of the analyst was generally greater than in theory it should be He could not say he had seen a single case in which psycho-analysis produced results which could not be obtained by other means

Dr H **CRICHTON-MILLER** said Freudism did not explain the creative factor in the mental life, but he thought psychologists should be ranged on the side of the coming principle

Prof **ROBERTSON** said he regarded Freud as one of the greatest discoverers the world had ever seen and held that much psychological literature, though clearly inspired by that great man, failed to render to his genius its due acknowledgment

Dr M A **ARCHDALE** and Dr T A. **ROSS** also spoke and Dr **POTTS** replied

The Maudsley lecture, an abstract of which appeared in THE LANCET last week, was delivered by Prof **ROBERTSON**

THE ANNUAL DINNER

The annual dinner of the Association, held at the Hotel Victoria, on Thursday, was well attended the chair being taken by Colonel J R Lord, the newly elected President

After the loyal toast Dr J Greig Soutar proposed "The London County Council," and described eloquently the various and far-reaching functions of that body, showing that, whatever they were, they all combined in the great aim of securing health for the people In his allusion to the maintenance by the Council of mental institutions, he included an applauded eulogy of Sir Frederick Mott Sir George Hume, chairman L C C, having briefly responded, Dr Percy Smith proposed 'Prosperity to the Universities and Royal Colleges," enumerating the long roll of educational centres nowadays implied by the toast, and drawing attention to the gratifying fact that many of them paid special heed to the development of psychological studies The toast was replied to by Prof G M Robertson, President of the Royal College of Physicians of Edinburgh and Maudsley lecturer of the Association, and Dr William Brown, Wilde Reader in Psychology, University of Oxford Dr Robertson traced eloquently the development of modern psychology from its start with Pinel, and his great pupil Esquirol, through Alexander Morison and others down to Mott, showed how the development went hand in hand with rising humanitarianism, until to-day we had, he claimed, mental hospitals that were a credit to the country Dr Bedford Pierce proposed "The Royal Society of Medicine and the British Medical Association," for which bodies Sir StClair Thomson and Sir Dawson Williams replied respectively, the second adding an eloquent tribute to the practical value of Mott's work. The toast of "The Guests," proposed by Sir Frederick Willis, was answered by the Rt Hon Hugh MacMillan, the chairman of the Royal Commission on Lunacy and Mental Disorder, who said that the report of that Commission was imminent, and would give no pleasure to certain critics of lunacy administration, although all his audience that evening might not be pleased with everything in the document The Bishop of Southwark also replied, and the evening closed with the toast of prosperity to the Association, proposed by Sir Arthur Robinson, Permanent

Secretary, Ministry of Health, and replied to by the President.

On Friday morning Dr **Norwood East**, medical inspector of H M Prisons, read a paper entitled Some Forensic Aspects of Epilepsy, which was discussed, and in the afternoon the President invited members and their friends to the Horton Mental Hospital, Epsom, where Colonel S P **James** and Mr P G **Shute** demonstrated the infection of mosquitoes and other processes in the treatment of G P I by malaria. Dr W D **Nicol**, the M.O in charge of this department at the hospital, also gave a demonstration.

ROYAL SOCIETY OF MEDICINE

SECTION OF ANÆSTHETICS

The meeting of this Section, reported in The Lancet of last week, was continued on July 15th, the chair being occupied by Dr F H **McMechan**, a visitor from the United States.

Dr **Wesley Bourne** read a paper on

Alleviation of the Acidosis of Anæsthesia.

It had been established, he said, that a true acidosis occurred in the anæsthesia produced by chloroform, ethyl chloride, ether, and—to a less extent—in that produced by ethylene and acetylene. The measure of a true acidosis was the lowering of the alkali reserve of the blood. Sodium and potassium were much increased in the urine after ether anæsthesia. The experimental observations indicated that phosphoric acid left the muscles during anæsthesia, and appeared in the liver until the resumption of the kidney function after the recovery of the animal, when it was redistributed and partially excreted. The ability of the liver to store this phosphoric acid seemed to depend on the degree of depression of the kidney function, and to be according to the depth of the narcosis. It had been suggested that the low alkali reserve and increased acidity of the blood in ether anæsthesia were due to the discharge of phosphoric acid from the muscles. The work on the subject done by the author and his colleagues included observations on human patients who were operated upon at the Western Hospital, Montreal. Patients who were given a phosphate solution had less nausea than control patients. It was best given per rectum immediately after operation, for when given by the mouth there was the risk that the patient might vomit the solution. As a result of giving phosphates, sleep was shortened.

Dr **Mary E Botsford** (California University) read a paper dealing with

Anæsthesia in Urological Surgery.

She said that it was well known that ether and chloroform inhibit kidney function. Cushing had regarded this as due to the reduced blood pressure and impaired aeration of the blood. In most cases of urological surgery requiring a general anæsthetic nitrous oxide was the best form, as it did not alter the blood pressure, except to cause a rise during secondary saturation when the oxygen percentage was reduced. Cystoscopies in adults were usually done under some form of local anæsthesia, and if a preliminary injection of morphine was found not to interfere with kidney function it would seem to be a valuable auxiliary, especially in getting muscular relaxation under gas anæsthesia. She gave a review of 76 cystoscopies on female patients which were done at the Children's Hospital, San Francisco, the ages ranging from 5 months to 72 years. Sixty-three patients were given nitrous oxide and oxygen, ten having varying amounts of ether in addition, and five straight ether with gas induction, and five were operated on under local anæsthesia. There was a noticeable retardation in the voluntary micturition in cases in which ether was used, a slight delay when atropine was given, and none when morphine alone had been administered.

Dr S R **Wilson** (Manchester) said that many years ago he gave up using morphia in cases of deep sections when nitrous oxide was employed.—Dr T P **Kirkpatrick** (Dublin) said that he had long noted that with ether anæsthesia the kidney function was inhibited. For general surgical operations patients did better with ether and recovered better if they did not have morphia.—Dr H. E **Featherstone** (Birmingham) agreed that early, quick, and uneventful recoveries from anæsthesia were more likely to take place in the absence of morphia, especially in cases in which the renal function was impaired. For prostatectomies he used nitrous oxide.—Dr **Samuel Johnston** (Toronto) considered that, clinically, morphine was a detriment to the average patient. There was the probability of giving too much of the anæsthetic of any kind, and when morphine had been given the patient did not react in the same way, nor did he recover so quickly. Some patients did not take ether at all well. For prostatectomy he used nitrous oxide and oxygen, with a small quantity of ether added.—Dr F E **Shipway** said that in the position of election for operation on the urino-genital system the respiratory movements should be as small as possible; he found that spinal anæsthesia gave the best results, with a small degree of general anæsthesia to keep the patient unconscious. Morphia and hyoscine were most excellent drugs to give beforehand—i e, 1/6 gr morphia, 1/100 gr hyoscine.—Dr. Z **Mennell** spoke of the difficulty of controlling the dosage when teaching students. He had never used morphia but he used atropine. Experience had enabled anæsthetists to disregard the statement, which had been copied from one text-book to another, that a small dose of atropine, without morphia, inhibited the kidneys from secreting urine.

Mr T P **Dunhill** (London) read a paper on

Anæsthesia in Goitre Operations.

He said that anæsthesia for patients suffering from the different forms of goitre required considerable versatility on the part of the anæsthetist. No one method was suitable for all forms. Always the patient's welfare must be the first consideration. For adenomata, single or multiple, unless of great size, general anæsthesia was as safe as for any operation in surgery; his own practice was to use endotracheal gas and oxygen. For removal of a large adenoma causing pressure he preferred local anæsthesia, but when it was deep in the thorax with moderate pressure there, he used endotracheal gas and oxygen, with a little ether. Nowadays chloroform was rarely given, but there were occasions on which it was the safest anæsthetic. For colloid goitre general anæsthesia was desirable. In exophthalmic goitre the operative death-rate 25 years ago was very high, and some of the deaths were due to the methods of anæsthesia then in vogue. The mortality was contributed to by operations on unsuitable cases, and at the wrong time, sometimes by the wrong surgeon. Patients ill with Graves's disease had but a small margin of safety, and usually chloroform was a dangerous drug to give. Ether, given skilfully, was safe for these cases. If the patient were a suitable subject gas-oxygen could safely be used or gas oxygen-ether, always provided that the right time was chosen and the surgeon did not attempt too much at one operation. It was not wise to attempt the operation at a time when the patient was in a state of great mental unrest. Local anæsthesia was best in the presence of auricular fibrillation. Chloroform gave the most comfortable anæsthesia for the surgeon, as breathing was quiet and bleeding was reduced to a minimum. But it was no more than reasonably safe, and this was not, in his view, sufficient. Ether, on the other hand, was very efficient and safe by the open method, the only objection being that the mask was a good deal in the surgeon's way. He thought it was wise to give an injection of morphine with atropine an hour before inducing general anæsthesia. Rectal anæsthesia had a field of usefulness, but a limited one.

cases of the disease, 25 gave evidence of hepatic derangement, most of the acute cases also showed a raised lipase content and a higher cholesterol content than the normal

Dr Farran-Ridge's paper dealt with the clinical manifestations of the disease as he had met with them in practice He said it was not surprising to see, in cases of encephalitis lethargica, symptoms of various psychoses reproduced, seeing that the epidemic disease might attack any part of the brain Especially did it mimic the manifestations of dementia præcox.

The Educational Adaptation of the Child

On Wednesday afternoon members accepted the invitation of Sir George Hume, the chairman of the London County Council, and his colleagues to meet at the County Hall to hear and discuss a paper by one of the medical officers, Dr F C Shrubsall, on Educational Adaptation of the Individual Child It consisted of a statement of the mechanisms and organisation set up by the L C C to get the best out of every child in the immense area covered by it, and to provide every provision and facility for backward and defective children The attention necessary to be given to the case of the parents was also stressed, while the children's physique was well looked after

The whole of Thursday morning was taken up with a debate on

Psycho-Analysis and its Development

The opening paper was read by Dr W A. Potts He said there was a mass of past experiences in the mind which could not readily be remembered, and processes went on in it which eluded the observation of the person concerned The modern psychologist said that the hidden mental processes were in the unconscious or the subconscious mind—i e, the inaccessible Freud, when dealing with neurotic and mental conditions, noted that some patients experienced relief and showed improvement when they were encouraged to talk frankly about their anxieties and difficulties, and he proceeded to work out a method of exploring the unconscious mind, which he named psycho-analysis The method showed to Freud the real motives of unusual and irregular conduct, and he became convinced that the unconscious mind consisted largely of unfortunate experiences in early life, of primitive instincts and desires, many of them sexual in character. Abnormal conduct was often a result of conflict between the conscious and the unconscious, because the demands of the moral code set up resulted in a repression of primitive desires Freud was convinced that not only a person's dreams, but the events of his whole mental life were due to definite causes, and were not the results of chance Sex was assigned the first place by this authority among these instincts, but with Freud sex has a wider significance than physical gratification, including such attributes as parental love Jung accepted Freud's dicta with modifications and attached a great deal of importance to the power of present ideas Dr. Potts explained that psycho-analysis was a reductive process, working down gradually to the pleasure principle operative in early childhood Dr Potts said it was most desirable that those who undertook to practise psycho-analysis should themselves have been subjected to the process by an expert Neither those of the Freud nor the Jung school subjected to psycho-analysis all who came to them The method was most suitable for cases of so-called neuroses and psycho-neuroses In some cases of incipient mental disorder, analysis would precipitate an acute condition He insisted that the physical condition of patients should always be investigated and treated

Dr W Brown (Oxford) expressed his general agreement with Dr Potts's paper He had himself been analysed, and he considered that the process as practised by the several schools was the same in quality But he contended that it would be difficult to find anybody who had been completely analysed He gave a brief sketch of Freud's most recent work on the libido theory

Dr A Wohlgemuth held the view that suggestion on the part of the analyst had much to do with the results claimed

Dr M. Hamblin Smith supported the claims of psycho-analysis, and gave the history of the attitude of the profession on these matters Many senior doctors entertained quite a strong bias against psychology Freud's system dealt with the normal as well as with the manifestations of the disordered mind Many sound and permanent results had been brought about directly by the practice of psycho-analysis, and much would be done in the prevention of mental troubles by the application of the knowledge now available

Dr. E Mapother said that what really concerned psychologists were the results of treatment, and the question which required to be answered was whether results were obtainable by the special methods of psycho-analysis which could not be attained otherwise After 20 years he was still in doubt The essence of the matter was free association and the attempt to trace anomalies to deviations of the infantile sexuality by that method Yet truly free association was scarcely ever attainable In practice the intervention of the analyst was generally greater than in theory it should be He could not say he had seen a single case in which psycho-analysis produced results which could not be obtained by other means

Dr H Crichton-Miller said Freudism did not explain the creative factor in the mental life but he thought psychologists should be ranged on the side of the coming principle

Prof Robertson said he regarded Freud as one of the greatest discoverers the world had ever seen and held that much psychological literature, though clearly inspired by that great man, failed to render to his genius its due acknowledgment

Dr M A. Archdale and Dr T A. Ross also spoke and Dr Potts replied

The Maudsley lecture, an abstract of which appeared in The Lancet last week, was delivered by Prof Robertson

THE ANNUAL DINNER

The annual dinner of the Association, held at the Hotel Victoria, on Thursday, was well attended the chair being taken by Colonel J R Lord, the newly elected President

After the loyal toast Dr J Greig Soutar proposed "The London County Council," and described eloquently the various and far-reaching functions of that body, showing that, whatever they were, they all combined in the great aim of securing health for the people In his allusion to the maintenance by the Council of mental institutions, he included an applauded eulogy of Sir Frederick Mott. Sir George Hume, chairman L C C, having briefly responded, Dr Percy Smith proposed 'Prosperity to the Universities and Royal Colleges,'' enumerating the long roll of educational centres nowadays implied by the toast, and drawing attention to the gratifying fact that many of them paid special heed to the development of psychological studies The toast was replied to by Prof G M Robertson, President of the Royal College of Physicians of Edinburgh and Maudsley lecturer of the Association, and Dr William Brown, Wilde Reader in Psychology, University of Oxford Dr Robertson traced eloquently the development of modern psychology from its start with Pinel, and his great pupil Esquirol, through Alexander Morison and others down to Mott, showed how the development went hand in hand with rising humanitarianism, until to-day we had, he claimed, mental hospitals that were a credit to the country Dr Bedford Pierce proposed "The Royal Society of Medicine and the British Medical Association," for which bodies Sir StClair Thomson and Sir Dawson Williams replied respectively, the second adding an eloquent tribute to the practical value of Mott's work. The toast of "The Guests," proposed by Sir Frederick Willis, was answered by the Rt. Hon Hugh MacMillan, the chairman of the Royal Commission on Lunacy and Mental Disorder, who said that the report of that Commission was imminent, and would give no pleasure to certain critics of lunacy administration, although all his audience that evening might not be pleased with everything in the document The Bishop of Southwark also replied, and the evening closed with the toast of prosperity to the Association, proposed by Sir Arthur Robinson, Permanent

THE GOLD TREATMENT OF TUBERCULOSIS.

SECOND REPORT BY THE MEDICAL RESEARCH COUNCIL.*

THIS second report deals almost entirely with clinical experience It does not attempt a review of the laboratory evidence on what is at the root of the whole inquiry—namely, the action of sanocrysin in arresting the spread of tuberculosis implanted experimentally into animals

The results are given briefly for each separate clinical centre at which the observations were made For convenience of reference the after-history of individual patients who were given by serial numbers in the first report [1] is here described under the same serial numbers No new reference numbers are given for fresh cases described in the present report

CLINICAL OBSERVATIONS

St Bartholomew's Hospital (Prof F R Fraser and Dr C F Harris) —Eleven cases of pulmonary tuberculosis have been treated or are undergoing the treatment Two cases of abdominal tuberculosis were treated and one case of lymphatic leukæmia was studied as a control The cases of pulmonary tuberculosis were all of a more chronic type than those in which the best results are reported from Denmark One death occurred after a few doses of sanocrysin, which were given only because a fatal issue seemed inevitable Severe reactions were experienced with large doses, but later it was found that with smaller initial doses at longer intervals the treatment was well tolerated No striking results have been obtained, but the unexpected improvement in certain cases suggest that sanocrysin may be of service in the early cases of pulmonary tuberculosis or in the fresh spread in more chronic cases The general impression has been formed that the method of treatment deserves further investigation

London Hospital (Prof Arthur Ellis) —Since the publication of the last report, only one new case of pulmonary tuberculosis has been treated This patient, whose condition was desperate at the time treatment was commenced, improved to a very remarkable extent The patient had been under observation in hospital for nearly a year and was going very rapidly down hill with hectic temperature, repeated hæmoptysis, and severe pleural pain At his own insistence a course of sanocrysin injections was given No severe reactions occurred and improvement was rapid and continuous He became afebrile, pain, cough, and hæmoptysis disappeared, his sputum diminished from four ounces daily to slight morning sputum only. He was discharged to a sanatorium and when last heard from some weeks ago was doing well

The after-histories of the cases detailed in the first report have been as follows —

CASE 1 —Has been in a sanatorium and is now back at home His general condition is much the same as on discharge, but the breath is now definitely fœtid and the moist sounds at the right base are much more numerous The cough and sputum have both increased There are no tubercle bacilli in the sputum

CASE 2 —Gradually failed, and died in his home in January, 1926 No post-mortem examination was obtained

CASE 3 —Downward progress continued He died early in June, 1925, five months after the last injection of sanocrysin Specimens of various viscera were obtained post mortem and sent to an analytical chemist for analysis for gold The kidney, liver, and colon contained no trace, but in a portion of the lower lobe of the left lung a definite trace of gold was detected, estimated roughly at 3 mg per 100 g of lung tissue The total gold salt used in this case was only 1 5 g

CASE 4 —Recovery from the exfoliative dermatitis eventually occurred Coincident with this, the exacerbation of the tuberculous process gradually subsided and the patient again became afebrile She is now able to be up and about, but the physical signs are more extensive and her general condition worse than before treatment was given It is some three months since she was last seen

CASE 7 (*Control*) —This patient was a case of Hodgkin's disease treated with sanocrysin as a control The patient died in January, 1926 No post-mortem examination was obtained

Prof Ellis considers that the value of the serum is doubtful He suggests that his bad results may have been due in part to serum All the cases that did badly had very severe serum sickness It was in the period of resulting prostration that exacerbation of the tuberculous process was particularly manifest

St Mary's Hospital (Prof F Langmead) —No new cases are reported With regard to the original cases—

CASE 9 —Convalescence was satisfactory The patient went to Ventnor for six months, where tubercle bacilli were present in the sputum at first Her health is now fairly good The sputum has been free from tubercle bacilli for some time, and radiograms show that there has been no spread of disease

CASE 10 —Satisfactory convalescence At work as a carman since August, 1925, and no tubercle bacilli in sputum A similar recovery had occurred previously, and before sanocrysin treatment, when the patient had been rested in a sanatorium

St Thomas's Hospital (Prof H MacLean and Dr G T Hebert) —Ten new cases have been treated with considerable, though it may prove to be only temporary, improvement Out of the five original cases, which were chosen as being of a mild type, two have relapsed decisively The after-history of all the original cases is as follows —

CASE 11 —Has kept well, no evidence of active tuberculosis, but is under treatment for pityriasis rosea

CASE 12 —Went to a sanatorium for three months, until June, 1925, tubercle bacilli in sputum at that time He was in good health three months later but not at work; then married and moved out of London, leaving no address

CASE 13 —Went to a sanatorium for three months, until July 8th, 1925, apyrexial, but tubercle bacilli in sputum at that time He worked in the country as a grocer's assistant till December, 1925, when symptoms of active disease reappeared In January, 1926, there was infiltration of both lungs, and in March, 1926, he was admitted to the Lambeth Hospital

CASE 14 —Went to a sanatorium for three months, until July, 1925 No further definite symptoms of tuberculosis The patient is now at work.

CASE 15 —Lived in the country during the summer of 1925 In September, 1925, was not looking well, but no tubercle bacilli were present in the sputum Patient had pleurisy of the left side in December, 1925, followed by symptoms of active pulmonary tuberculosis Admitted to a sanatorium in February, 1926

University College Hospital (Prof T R Elliott) —Twelve cases of tuberculosis have been treated, including the four described in the first report Three were of glandular or osseous infection and gave no special information There were seven patients with pulmonary tuberculosis

CASE 16 —In the first report it was concluded that the girl had been made worse by the treatment After discharge from hospital she remained at home in a poor environment But she is now well and back at work There are no tubercle bacilli in the sputum, and the disease appears to be completely arrested, an unexpectedly good recovery in view of her originally poor physique

CASE 18 —The patient returned to work soon after discharge from hospital and remains well

CASE 19 —The boy went to work with very long hours in a factory last autumn His health broke down and he was readmitted to hospital There appeared to be more extensive fibrosis in the lungs, but there were no tubercle bacilli in the sputum He recovered quickly and was then sent to the country

One new case of pulmonary tuberculosis developed very serious jaundice, with clay-coloured stools, after two doses of 0 5 g and 1 g respectively Recovery from the hepatitis was slow and treatment was, therefore, discontinued Such toxic jaundice appears to be rare in Danish experience A similar but fatal

---

[*] The first report appeared in THE LANCET of April 18th, 1925, p 833

EDINBURGH MEDICO-CHIRURGICAL SOCIETY

AT a meeting of this Society held on July 7th Prof W. **RUSSELL**, the President, took the chair, and Prof R. **STOCKMAN** opened a discussion on

Rheumatoid Arthritis

This disease, he said, was sufficiently familiar to need no formal definition A bewildering number of names had been given to it, but though the name rheumatoid arthritis had been criticised, at least it gave some clue to the nature of the disease. It was reasonably certain that under this one term were included the results of the activities of a number of different but closely allied microbes, and until these had been identified it was best to be content with a general clinical designation There was little doubt that the cause of rheumatoid arthritis was an infection of low virulence and great tenacity Occasionally organisms had been found in the joints, but as a rule attempts to find them either in joints or blood had proved fruitless That there were different forms was shown by the varying clinical courses of the disease—one form starting in the fingers and spreading to other joints, whilst another began an acute course in a larger joint Sometimes glands and spleen showed enlargement, and in fact all forms presented the aspect of a low chronic septicæmia The disease ran a more or less lengthy course, relieved by occasional exacerbations, finally coming to an end but leaving permanent damage in its wake The main attack was on the white fibrous tissue of the locomotor system It caused a great deal of general stiffness, aching, and pain quite apart from the joints which was due to perineuritis in the inflamed connective tissue In certain cases, however, the bones seem to be attacked more than in others The remaining well-known symptoms—muscular atrophy, deformity of bone, and contractures—were really sequelæ of the original disease The infection was in all probability acquired through the alimentary and other open tracts and through the skin, in the majority of cases a septic focus could not be traced, but often arthritis followed tonsillitis or some other septic condition, whilst connexion with a skin disease, such as psoriasis, was often proved

Treatment, said Prof Stockman, resolved itself into combating the infection, removing fibrositis, and correcting contractures No known drug was specific, and until recently treatment had been carried out on general tonic lines with liniments, baths, and massage, which lessened the stiffness and pain, but did not check the disease Vaccines had been extensively used, but were not of proved specific value The one treatment of real value was that known as protein shock or non-specific protein therapy, the benefit of which appeared to depend on the sharp feverish reaction following injection, which seemed to raise the defensive powers of the body Personally he used the typhoid bacillus as being most satisfactory; beginning with a dose of 100 millions intravenously, the treatment was repeated every six days until six injections had been given, the dose being gradually raised to 200 or 250 millions The reaction began within an hour with a rigor and a rise of temperature to 103°–105° F, followed by uncomfortable heat, then profuse perspiration and a return to normal, the whole reaction lasting from six to twelve hours There was also a marked focal reaction with pain in the affected joints and fibrositic areas Occasionally there was herpes at the mouth and slight albuminuria A febrile reaction, if any, usually settled after the third or fourth injection The whole proceeding, while disagreeable at the time, was perfectly safe and was followed by a feeling of increased well-being

Dr G L **KERR PRINGLE** (Harrogate) said that, although fully alive to the association of infective foci with arthritis, he thought that such factors as soil and diathesis were too often forgotten Not everyone who had a septic focus suffered from arthritis, nor did an injury to a joint always produce osteo-arthritis The commencement and cessation of menstruation were associated with the disease Pregnancy had long been considered a cause, and many arthritics who became pregnant claimed that their arthritis improved during pregnancy, only to return with increased severity after parturition. It had been found that glucose tolerance is lowered in most cases of proliferative arthritis, and that when a septic focus is removed the tolerance becomes more normal, and also that these cases improve on a low carbohydrate diet This last was an important point in treatment, and the patients should be fed on red meats, green vegetables, and fruit Basal metabolism did not appear to be altered There was evidence that achlorhydria allows streptococci to multiply more readily in the bowel, and it might therefore be an accessory factor in the disease

Infective foci, continued Dr Pringle, should be removed If achlorhydria was present hydrochloric acid should be given In young women with abnormal menstrual history thyroid extract might be administered in small doses along with the French tincture of iodine in increasing doses for long periods, the patient being on a low carbohydrate diet. Where there was intestinal stasis lavage was often helpful A daily record of temperature and a weekly record of weight ought to be kept, the patient should be as much as possible in the fresh air, and local movement should be encouraged Radiant heat, hot air baths and local steam baths, paraffin-wax baths, or hot douching produced local hyperæmia, which should be followed by massage to the wasted muscles It was often advisable to place the limb after massage in a trough splint with a little extension Where there was effusion, repeated aspiration with a large hypodermic needle relieved pain and prevented distension of the capsule and stretching of ligaments Hot mineral water baths followed by hot packs produced sweating, slightly raised the temperature, dilated the capillaries, relaxed the muscles, and often induced sleep In the sequelæ of the disease the memory of pains experienced was difficult to eradicate, encouragement was very necessary, and each case and each joint must be considered individually Semi-flexed knee-joints should be straightened, and if massage and hot baking would not bring about the desired effect, tenotomy, synovectomy, or other surgical measures must be considered Nothing surgical should be attempted where active disease was present A glucose-tolerance test was a good index, if the tolerance was lower than normal operation should not be attempted The use of vaccines in arthritis Dr Pringle considered uncertain Wonderful results were sometimes obtained, but sometimes they were very disappointing His own experience of intravenous injection of T A B was limited Strasser, of Vienna, pointed out that the whole object of intensive treatment, whether by protein or sweating baths, was to substitute for the chronic infective or metabolic process a slightly more acute and favourable phase

Dr W T **RITCHIE** said that fibrositis was a very common condition from which everybody suffered at times Rheumatoid arthritis, in proportion, was much less common, the connexion between the two conditions was obscure The path of infection, he thought, was often by the pelvic organs, and the prostatic secretion especially should be investigated Peptone shock was disappointing—Dr **DAVID HUSKIE** believed that calcium metabolism was involved He saw no reason why a full diet should not be given, including red meat, a food usually excluded from the diet—Dr J M **BOWIE** recommended prolonged treatment by iodine In his own experience he had found colon lavage and thyroid of little use—Dr **ALEXANDER GOODALL** thought that if improvement was to occur it would be seen very early in treatment—Dr **JOHN EASON** took the opposite view, stating that frequently improvement was only seen after treatment had been persevered with for some time He suggested that exhaustion, especially that incurred in sick nursing, might be a cause sputum, and he was later admitted to hospital A second course of 2 25 g. was given in November The patient has regained weight and is now capable of light graded work

Two cases of extensive and obviously grave pulmonary tuberculosis, aged 14 and 15 respectively, died two or three months after sanocrysin treatment, which did not appear to have influenced the illness in any markedly unfavourable way One of Dr Watson's cases developed exfoliative dermatitis, presumably from metallic poisoning, after 6 25 g Dr Tattersall's patients had all given fairly good results Prof Cummins, apart from the two expected deaths in toxic cases, had four favourable results 'There was dramatic and rapid improvement in each of them after a short course of sanocrysin The tubercle bacilli disappeared from the sputum and the weight after treatment got back to or outstripped the highest known weight This favourable change, though not persistent, was maintained for several months after the course of treatment " Prof Cummins concludes that sanocrysin, *judiciously used*, is a valuable means for raising the less advanced type of "hospital" case up to a "sanatorium" level, and perhaps for the actual cure of some cases of a more favourable clinical type

Royal Infirmary, Edinburgh (Prof Sir Robert Philip and Prof D Murray Lyon) —Twenty-two cases of tuberculosis have been treated by means of sanocrysin Undoubted cases of tuberculosis were selected who had already benefited by institutional treatment All cases were afebrile , 17 were examples of pulmonary tuberculosis with tubercle bacilli in the sputum The lesions ranged from slight localised nodules to extensive cavity formation or marked fibrosis The series examined also included two cases of tuberculosis of the glands, one of renal tuberculosis, and two of lupus Other therapeutic measures were discontinued during the trial of sanocrysin Eight patients had previously had more or less prolonged treatment with tuberculin by percutaneous method The patients received from two to ten injections of sanocrysin, the most usual number being six The quantities of sanocrysin administered have varied from 1 5 g to 10 g In all cases the initial dose was 0 5 g and subsequent injections have usually been 1 g Anti-tuberculous serum was given in ten of the cases and in small quantities only (doses of 20–40 c cm), but its use was not encouraging

Considering first the five cases of non-pulmonary tuberculosis, the renal case was unimproved One case of tuberculosis of the glands was improved, the glands becoming more discrete and distinctly smaller , in the other case the treatment had to be discontinued owing to severe local inflammation The two cases of lupus after each injection of sanocrysin exhibited a considerable congestion in and around the affected area Later, the scales practically disappeared and the centres of the lesions became pale as if cicatrisation had increased The margins, however, remained red and raised in nodules When last seen two months after the beginning of treatment, both cases had relapsed, the lupus areas appearing active and heavily encrusted On the 17 cases of pulmonary tuberculosis the treatment had to be discontinued in seven cases, in three because of the severity of the reactions, and in four others on account of the discomfort and distress experienced by the patients Of the ten cases that underwent the full course, seven ultimately showed decided improvement when examined from five to ten months after the termination of treatment One, who was apparently doing well, subsequently had several attacks of hæmoptysis and died

In studying the effects of the sanocrysin treatment of tuberculosis, the Edinburgh workers state that the principal questions to be answered are (1) Whether sanocrysin possesses any specific action against tuberculous tissues (2) Whether its employment has benefited the patients subjected to it (3) Whether the present method of administration is the most suitable

(1) It is observed that the reactions which follow the administration of sanocrysin might arise in different ways (*a*) The drug, unchanged or chemically altered, may act on the tissues directly , (*b*) as a result of a selective action of the gold on tuberculous tissues and organisms, specific toxins might be liberated The resultant reactions might be termed "gold" effects and "tuberculin" effects respectively The evidence suggests that the focal reactions, the increase of sputum, the papulo-erythematous skin eruptions, the pyrexia, and the gastric symptoms, especially vomiting, which the authors noted accompanied the earlier doses of sanocrysin in a course may be regarded as "tuberculin" effects On the other hand, the albuminuria which occurs late in the course and in association with desquamative skin lesions and many of the alimentary symptoms (stomatitis and diarrhœa), appears to be a "gold" effect due to irritation accompanying the accumulation of the metal in the renal cells The gold salt, therefore, appears to produce two types of effect in the body, the "specific" action on tuberculous areas which is immediate, and the cumulative poisoning seen in the excretory organs The authors add that two questions still remain unsolved—namely, the cause of the early decline of the "tuberculin" reactions, and the reason for the failure of later doses of sanocrysin to evoke albuminuria

(2) The immediate effects on the health of the patients have varied greatly. The majority have experienced more or less discomfort and some have suffered severely The gastric symptoms and tendency to severe dermatitis combined with the almost universal and often considerable loss of weight make the treatment a matter not lightly to be undertaken in its present form To avoid the risk of producing severe reactions it would appear desirable to aim at a smaller concentration of sanocrysin in the system, either by reducing the size of the dose, or by lengthening the interval between the doses, or by combining these suggestions In several cases a striking reduction has occurred in the number of tubercle bacilli in the sputum Negative films became more frequent in some patients, but in no instance did the bacilli permanently disappear from the sputum, and, as yet, no patient can be said to have had his disease arrested Apart from the loss of weight produced no patient has been harmed by the course of treatment The one death that occurred is not ascribed to the treatment, as it took place after the full course had been completed with apparent benefit at first resulting Some degree of clinical improvement has been observed in the greater proportion of patients who underwent the full course No dramatic change has occurred, but there has been in several instances a steady advance at a greater rate than might otherwise have been expected This improvement has not in all cases been maintained , some of those who did best during the course have since retrogressed, whilst others who did not seem immediately benefited have since greatly improved

(3) The authors conclude their report by some observations on the intramuscular administration of sanocrysin They formed the impression that this method presented some advantages—e g , less albuminuria and less rapid loss of weight, and that further experience was likely to reveal ways of still further excluding the discomfort of the procedure

Edinburgh Public Health Department (Dr J Guy) —Dr Guy has treated ten cases of pulmonary tuberculosis with sanocrysin The first six were given small and gradually increasing doses, and the last four received large doses, but not the full doses recommended by Prof Mollgaard In the first six of the series sanocrysin did not appear to have any appreciable effect for good or ill In the last four there appeared to be some slight improvement and lessening of the sputum This, however, is a regular feature of sanatorium régime Dr Guy considers that so far there does not appear to be any marked curative effect from sanocrysin He infers that the drug has case was described (Case 8 from St Mary's Hospital) in the first report Another patient with extensive caseous lesions in the left lung and only two months' history improved with great rapidity under treatment The fever ceased after two severe rash reactions, and ultimately the tubercle bacilli disappeared from the sputum Three months later a relapse occurred at a sanatorium during December The patient was readmitted to hospital with further spread in the lungs and tuberculous laryngitis A second course of sanocrysin failed to evoke a rash or high pyrexia The patient is still under treatment and appears to be improving only slightly One control case was tried, a woman, aged 25, with prolonged fever ranging daily from 99°–101° F and high eosinophilia (60 per cent), of unknown cause Three injections of 0 5 g each were given, no rash resulted nor any obvious temperature change The best results in tuberculous infections seem to have been obtained when the patient reacted strongly with fever and a rash Prof Elliott concludes that the treatment is definitely beneficial in early cases without extensive fibrosis, though it is rarely capable of effecting a rapid and complete arrest of tuberculous disease[2]

Guy's Hospital (Dr G Marshall) —Sanocrysin had not been used at this centre at the time of the first report During the last year eight cases of pulmonary tuberculosis have received treatment All these cases had extensive pulmonary disease and were of some length of duration Three cases showed apparent arrest, two cases improved, while the remaining three cases were unimproved In no instance was the disease extended by the treatment The improvement resulted after other modes of treatment such as rest and sanatorium were tried and failed Severe reactions with exanthem and albuminuria have been observed although small doses were employed One case of infective endocarditis, in which the spleen diminished in size and became impalpable, ceased treatment after 11 doses In addition, provocative diagnostic doses of sanocrysin have been given to three patients It is considered that sanocrysin has a beneficial effect when used with discretion and is likely to become a part of the routine treatment in selected cases of pulmonary tuberculosis

Brompton Hospital for Consumption and Diseases of the Chest (Dr L S T Burrell) —At this centre, also, observations had not been commenced at the date of the first report a year ago Twenty cases were selected for treatment as being patients who were getting worse or had failed to improve after other methods had been tried These form the large group of fibrotic or fibro-caseous cases, slowly progressive with frequent relapses and periods of improvement. Time will show whether or not the progress of disease can be checked in these cases by sanocrysin, and in this report it is only the immediate result that can be shown

In the first five cases in the series artificial pneumothorax had been induced with very good initial results In each case, however, there had been a relapse with return of sputum containing tubercle bacilli After a short period of treatment with sanocrysin one patient was slightly worse The other four improved, two of them losing the tubercle bacilli from the sputum The next eight cases (Nos 6–13) were of the fibro-caseous type In all, sputum containing tubercle bacilli was present After sanocrysin the number of tubercle bacilli in the sputum was reduced in every case, and in four they disappeared altogether, though they reappeared in two of these In another case (No 14) there was long-standing disease complicated by a chronic pleural effusion, which was converted into a hydropneumothorax Sanocrysin was given in order to control the disease in the other lung, but it had no apparent result, either good or bad No 15 was one of spontaneous pneumothorax, and again the sanocrysin was given in an attempt to improve the condition of the other lung The patient, however, became worse In the final five cases there was bilateral disease; the worse lung was treated by artificial pneumothorax, and sanocrysin was also given in the hope that it would have a good effect on the disease in the other lung Of these five cases the tubercle bacilli disappeared from the sputum in four (though in one they reappeared) and in the other they were much reduced in number. This result, however was probably due largely to the pneumothorax, and in one case (No 16) the tubercle bacilli disappeared after the pneumothorax had been induced but before the sanocrysin was started

The sanocrysin was given intravenously and the initial dose was 0 25 g This was followed a few days or a week later by 0 5 g, then 0 75 g, and finally 1 g This was the maximum dose given and was repeated weekly It was noticed that in many cases no reaction occurred until a dose of 0 75 g or 1 g was reached, and that the reaction got less on subsequent injections. In two cases small doses (0 1 g) were given daily for a week and then this course repeated after a week's interval This method had no effect in one case, and in the other it produced slight albuminuria, pains in the limbs and disappearance of tubercle bacilli from the sputum This method of giving frequent small doses might possibly be of advantage in acute cases

Taking the 20 cases as a whole, two became worse and 18 improved or remained unchanged In ten cases tubercle bacilli disappeared from the sputum, although in three of these they reappeared In five cases there was no reaction after the injections. Rigors occurred in nine cases, and a slight evening rise of temperature with shivering and malaise was also noted after some of the injections A long febrile reaction was seen in only two cases (Nos 1 and 13) An erythematous rash occurred in four cases Vomiting a few hours after the injection in nine cases Pain in the limbs was present in four cases Albuminuria was noted in three cases only and was very slight and transient One patient complained of a metallic taste in the mouth and small blisters appeared on the mucous membrane of the mouth

Warwickshire King Edward VII Memorial Sanatorium, Warwick (Dr F R G Heaf) —Twenty patients suffering from pulmonary tuberculosis (all stages, with tubercle bacilli present in the sputum) have been treated with sanocrysin, and six are still under treatment Of the 20 patients, two left before the course of treatment was completed, and in two cases treatment was stopped owing to the advanced state of the disease Of the 16 remaining cases, ten were regarded as quiescent at the termination of treatment, tubercle bacilli being absent from the sputum and X ray evidence and physical examination indicating marked improvement; one was improved, but tubercle bacilli were still present, two showed no alteration, and three were worse In two cases sanocrysin was given in conjunction with artificial pneumothorax treatment, and the progress of a recent lesion on the side opposite to the collapsed lung was arrested Dr Heaf hopes to be able to report on the after-history of the patients at the expiration of one year He concludes that sanocrysin arrests the early progressive lesion but has little or no effect upon lesions associated with fibrosis

Wales (Prof S Lyle Cummins) —Sanocrysin has been tried at three centres in Wales under the general supervision of Prof S L Cummins In all, 16 cases have been fully treated as follows Glan Ely Hospital, Cardiff Prof Cummins, six cases, Dr A. Brownlee, Cymla Hospital, Neath one case Dr N Tattersall, South Wales Sanatorium, Talgarth six cases Dr H E Watson, three cases

Details of the individual cases and their results are given elsewhere[3] by Prof Cummins and Dr Tattersall In regard to the after-history of the cases quoted in the original report a year ago—

CASE 21 —The patient was sent to a sanatorium Sputum was negative for a time, but in July became positive Two more doses, 0 5 g and 1 g, were given. Tubercle bacilli disappeared from the sputum and the patient regained weight. He now has persistent albuminuria.

CASE 22 —The patient returned to work at a colliery in April, 1925. In July tubercle bacilli appeared again in the

Reviews and Notices of Books.

HEART DISEASE

Les Angines de Poitrine By Dr LOUIS GALLAVARDIN, Médicin des Hôpitaux de Lyon Paris. Masson et Cie Pp 181 Fr 25

THE main part of this book consists of a review of angina pectoris, based on the author's own personal observations on 791 cases, and presented at the eighteenth French Congress of Medicine in 1925 A final section is devoted to the discussion of points of interest arising out of the records of a series of 20 cases which came to autopsy The difficulties of this subject are fairly faced by Dr Gallavardin, who has chosen to regard it as one might regard the broad subject of dyspnœa. A cry of distress is heard, but the underlying disease is multiform. This was also James Mackenzie's attitude, though many authors have preferred not to include all pain of cardiac origin under the term angina pectoris, and it is not customary to do so in this country The author holds to his statement that there are grave and there are benign anginas Perhaps the book gains by this aspect, for it is based on his extensive observations of patients all of whom had pain

In the opening chapter the author refers to the uncertainty of quantitative diagnosis in a condition where the symptoms rather than the objective signs constitute the central feature of the picture He differentiates true angina from the other forms of cardiac pain and classifies his cases into three groups (1) organic, (2) doubtful, and (3) nervous In the organic cases some structural cardiac or aortic lesion was present This group includes 617 cases and is further subdivided into (*a*) those (486) cases in which pain was brought on by exertion, (*b*) those cases in which the attacks occurred only during rest or at night; and (*c*) those cases in which the association with other special symptoms such as dyspnœa suggested a different ætiological factor and appeared to justify classification in a separate group Into the second main group—i e the cases of doubtful significance—Dr Gallavardin places 174 cases in which the clinical picture was atypical. In 52 of these pain occurred on exertion, and in the remaining 72 only at rest or at night As to the nervous type, the author reviews the evidence for the existence of a benign type of angina; he is of opinion that such cases do undoubtedly exist, and that in them the condition is probably due to hyper-excitability rather than to hyper-excitation of the nervous system His 50 cases in this group comprise 30 men and 20 women —a very high male incidence which is probably attributable to the rigid standard which he has adopted in separating angina from other types of cardiac pain. The diagnosis of "angina névrosique" must be based chiefly on the history, since in some cases of true angina physical signs are absent. The special points to be noted are the multiplicity of manifestations or, as Dr Gallavardin aptly expresses it, the "exuberance of symptoms," and secondly the absence of any quantitative relation between pain and the amount of effort required to induce it.

In the section of the book devoted to pathogenic considerations the author inclines to the view that the majority of cases are attributable to spasm of the coronary arteries, and points out that in 12 out of 20 autopsies on cases of angina a coronary lesion was present. In 25 cases, on the other hand, where post-mortem examination revealed infarction of the heart, anginal symptoms occurred in three only Spasm of the coronary arteries may be compared with spasm which occurs in the limb arteries of patients with intermittent claudication, and just as infarction of the heart may occur without angina, so in the majority of cases of senile gangrene there is no previous history of intermittent claudication. In conclusion the author points out that any benefit likely to be derived from surgical measures in the treatment of angina lies not in the hope of relieving the pain, but of interrupting the reflex path responsible for producing coronary spasm

This small book is written in a fluent style by one of the most esteemed French authorities on heart disease It is easy and interesting to read, it conveys the author's own experience and deductions, and we welcome it as a valuable contribution to a complex subject

---

Modern Methods in the Diagnosis and Treatment of Heart Disease Second edition By FRANCIS HEATHERLEY, M B, B S Lond, F R C S, Superintendent, Heart Clinic, Manchester; and Cardiologist to the Ministry of Pensions London Baillière, Tindall and Cox 1926 Pp 269 *8s 6d*

IN the second edition of his book on modern methods in heart disease Dr Heatherley adds two new chapters. of these the first deals with blood pressure and the second with treatment of cases of the effort syndrome The author states in his preface that the purpose of the chapter on blood pressure is to awake the interest of the general practitioner and to stimulate him to play his part in making original observations which will help forward the advancement of knowledge by affording data on which to base statistics. Dr Heatherley gives a clear description of the auscultatory method of blood pressure estimation and refers to several points which have proved of interest to him and which are likely to be unfamiliar to many practitioners In this chapter the ten pages which are devoted to the general principles of research contain many maxims worthy of the attention of those who have had no previous experience of original work

An appendix, dealing with hints to patients on the home treatment of functional disorders of the heart, consists of a brief popular account of the nature of functional nervous disorders and their treatment This appendix, which the author states to be largely based on Dr Geikie Cobb's Manual of Neurasthenia, has been distributed to pensioners attending the Manchester Heart Clinic, and has been found of value in obtaining their intelligent coöperation in the matter of treatment Dr Heatherley's book would be improved by a bibliography containing references to the numerous authorities quoted in the text, in place of the "list of interesting books" which it at present contains

The book is pleasantly written and will be of interest to those who are concerned with the medical examination of pensioners

BAINBRIDGE AND MENZIES' ESSENTIALS OF PHYSIOLOGY.

Fifth edition Edited and revised by C LOVATT EVANS, D Sc Lond, M R C S, L R C P, F R S, Professor of Physiology, University of London, at St Bartholomew's Medical College London: Longmans, Green and Co 1925 Pp 508 *14s*

THE progress of physiology is so rapid that not only the larger and more discursive but also the smaller condensed text-books require constant revision We welcome, therefore, a new edition of Bainbridge and Menzies' well-known work, brought up to date by Prof Lovatt Evans The merits of the book have long been recognised, and it is hardly necessary to add that the revision in such competent hands has been well done. Students preparing for pass examinations in physiology will find more help in this volume than in many larger tomes, and may be confident that they are being kept abreast of present-day discoveries

Considerable additions have been made, and as unessential details had in previous editions been reduced to a minimum, deletions have been rare. The popularity which this book already enjoys will doubtless be retained if not enhanced by the appearance of this new edition.

some specific effect on the tuberculous lesion, as in the last four cases treated signs of increased moisture were commonly noted after the injection He regards sanocrysin as worthy of further trial

Northern Ireland (Dr A Trimble and others) —A committee was constituted last year to supervise the trial in the Belfast area of sanocrysin as a method of treatment of tuberculosis The reports from the three institutions selected for the test are thus summarised —

Belfast Municipal Sanatorium (Dr Percy Walker) Six male patients treated Each patient received seven injections, totalling 6 5 g each All these patients were suffering from pulmonary tuberculosis (Turban-Gerhardt · third stage) Result One case appears to be arrested, two are definitely greatly improved, the sputum being now negative as regards tubercle bacilli, two are improved clinically but the sputum is still positive One case shows no change A second group of three patients is still undergoing treatment

Forster Green Hospital (Dr B R Clarke) —Twelve cases of pulmonary tuberculosis treated, 11 with tubercle bacilli in the sputum Results · The sputum of four patients became negative, four patients had a diminished number of tubercle bacilli, and in two patients there was an actual increase of tubercle bacilli after treatment Clinically, eight of the 12 patients showed improvement, the condition of two was unchanged, and two appeared to be worse as a result of the treatment Five further cases are undergoing treatment

Royal Victoria Hospital (Dr S I Turkington) —Four cases of pulmonary tuberculosis treated Three cases were definitely improved, in two of these cases tubercle bacilli disappeared from the sputum after treatment The fourth patient had a profound reaction after the third dose of sanocrysin and died from toxæmia Serum was used in this case but it had no beneficial effect

The *conclusions* of the Belfast Committee are as follows · (1) Sanocrysin is a distinct therapeutic advance in the treatment of tuberculosis in definitely selected classes of cases (2) The undoubtedly good results that have been obtained must, however, be observed for a further term, say, at least one year, to see whether the results are permanent, or whether further courses are advisable (3) Sanocrysin as a method of treatment is not suitable for general use, and with our present limited knowledge it should only be used in institutions equipped with the necessary apparatus, and under the direct control of sufficiently experienced physicians, with expert knowledge in the treatment of tuberculosis (4) Further research is necessary in order to determine (*a*) the class of case most likely to benefit by this form of treatment, (*b*) the correct size of dose for individual patients, (*c*) the intervals between the doses; (*d*) the length of the whole course of treatment, and (*e*) the significance of the clinical phenomena which would seem to indicate the discontinuance of the treatment

GENERAL SUMMARY

Experience in the selection and treatment of cases has greatly lessened the dangers attending the use of sanocrysin The first collective report by the Medical Research Council described two deaths directly caused by sanocrysin out of a total of about 30 cases treated This second report records only one similar fatality (Royal Victoria Hospital, Belfast) in a much larger number of cases treated, about 140 But the risk remains There may be sudden or progressive exaggeration of the more serious symptoms of the tuberculous infection, or there may be a poisoning of the kidney, of the liver, and even of the skin with a drug dermatitis which is quite distinct from the relatively transient rash All these dangerous features are far more liable to arise in the sanocrysin treatment of tuberculous patients than in the use of salvarsan for syphilitic or other infections All patients under treatment must, therefore, be in bed and under close medical control

In the last 12 months it has become the custom to give smaller doses of sanocrysin and at longer intervals than those used with the cases described in the first report The patient is thereby spared from dangerous reactions and even from any great discomfort It is, however, debatable whether this attenuation of the treatment for the sake of the patient's immediate welfare may not have the disadvantage of lessening the final benefit The arguments on either side are given in two recent books by Secher [4] and Wurtzen [5] respectively, when describing clinical results obtained in Copenhagen

The special serum has rarely been used and there is no fresh experience to record about it Nor is there much more evidence upon the question whether a well-marked reaction to sanocrysin can be accepted as a diagnostic test for tuberculous infection It would, indeed, appear from the reactions seen by Fournier and Mollaret [6] in the treatment of human syphilis with a similar gold salt that such reactions are not specific for tuberculosis

As in the first report, it was again evident that there may be an advantage in collecting evidence from different clinical observers as to the possible benefit of sanocrysin treatment Some thought that nothing more was seen than might have been expected as the result of prolonged rest under hospital or sanatorium control But others were very emphatically of the opinion that sanocrysin did cause unusually quick amelioration of all the features of a tuberculous infection, especially in the lessening of sputum and disappearance of tubercle bacilli The question of secondary infections of the lung tissue by other organisms has not been dealt with The results described are considered only in the broad aspect of clinical recovery or deterioration, for there are no laboratory tests yet available for analysis of any possible changes in a patient's powers of resistance to tuberculous infection

The Medical Research Council received by the generous courtesy of Prof Mollgaard a free supply of sanocrysin and serum for trial in Great Britain over a period of 12 months The trial has shown how dangers may be averted, and, in the opinion of some workers, it has given indication that along the line of some such substance as sanocrysin there is definite hope of a drug treatment that will check the progress of a tuberculous infection and allow the patient's natural powers of resistance better play in finally arresting the disease These various clinical reports, for which the Council are greatly indebted to the observers, will suffice to indicate to the medical profession the general need for extreme care in the use of sanocrysin and the particular types of infection in which it may be expected to cause some improvement.

PAYING PATIENTS OF LIMITED MEANS —The trustees of the late Colonel John C Barlow have allocated a sum of £65,000 to the enlargement and improvement of Bury (Lancashire) Infirmary The conditions attached to the gift require the provision of accommodation for persons of limited means as private paying patients The extensions will provide more women's beds, a maternity department, and the erection and equipment of a new electro-massage, X ray, and sunlight treatment department. There will be 11 private nursing rooms, with an operating theatre attached, for paying patients, who will be entitled to be attended by their own doctors

THE LANCET.

LONDON: SATURDAY, JULY 24, 1926.

THE TREATMENT OF INSANITY.

THE meeting of the Royal Medico-Psychological Association, held July 13th–16th under the presidency of Colonel J. R. LORD, proved the existence both within and without the medical profession of a valuable extension of interest in this most important section of medicine. We published last week an abstract of the Maudsley lecture delivered before the Association by Prof. G. M. ROBERTSON, who took as his subject the most practical side of mental therapeutics—namely, the prevention of mental disease; and certain of his words, though not intended so to do, formed an excellent illustration of the grave and delicate responsibilities of the psychiatrist. Prophylaxis might be defined, said Prof. ROBERTSON, as the prevention of an attack of insanity when it threatened but before definite symptoms had appeared; and the anxious position in which the medical practitioner, not necessarily an expert, is placed, when dealing with possibly unstable patients, is well indicated by the definition. How does an attack of insanity threaten before definite symptoms appear? In words which formed a preliminary survey of the whole field Prof. ROBERTSON enumerated the danger signals, and the particular skill of the diagnostician may be said to come in when a difference can be established between a danger signal and a definite symptom. For example, suppose a change of character is recognised by the physician from personal observation, supported or no by a family story. Is this change of character the evidence of an established form of mental disease, or is it only an indication that such disease will be established if preventive measures, and those of the right sort, are not undertaken?

Here we have to consider the fundamental oppositions of view that are found among equally learned psychiatrists as to the inevitability of certain prodromata being followed by sinister sequelæ. A jesting story has it that a parent having an open mind on religious questions and becoming the progenitor of twins, decided to have one child baptised and the other not, keeping the second one as a control. This is a fair burlesque of the situation which arises in medicine when we desire to prove or disprove the efficacy of any particular procedure; but the medical conscience would not allow the practitioner to offer prophylaxis to certain cases and to withhold it from others in order to ascertain which the right course might be in the future. He must subject all the sufferers alike to what he believes to be the best treatment, and the general practitioner will find that he cannot obtain identical advice from equally competent experts as to where and how to begin prophylactic attention, or even as to whether we should begin it at all. We publish this week, as a Special Supplement to THE LANCET, a symposium on Early Mental Disease written by a group of well-known authorities, the main object of the Supplement being to answer questions that arise in the minds of medical practitioners who are called in to pronounce upon the normality or the certifiability of a patient who has manifested mental instability, disorder or development. The plan on which the collaborators agreed to arrange their contributions was chosen because it appeared to be one in which exact information upon any particular case could be easily obtained, whether the guidance was required for the making of a diagnosis, or for the selection of treatment. Thus the first part of the volume is devoted to the study of those early symptoms which, if persistent and progressive, should lead the practitioner to suspect instability, while the second part gives an account of the psychoses and neuropsychoses met with in practice, and there is furnished here the evidence that certain preludes, if unseen or neglected, result in various forms of disaster. The essays were submitted in their collected form to the late Sir FREDERICK MOTT, whose preface points out that the most important possession for the general practitioner is a knowledge of the signs and symptoms of mental defect or disorder at the earliest possible moment, and who has commended the volume to the medical profession because it should meet many of the anxious positions now existent.

Dr. R. H. COLE, writing on the progress of the medical profession in the practice of psychiatry in this issue of THE LANCET, calls particular attention to the advancement that has been made during the last 30 or 40 years in its teaching. His words have a wide significance. We find specialists regretting the small experience of the general practitioner in medico-psychology, and it is well to be reminded by one of them that it is only during the last generation that the training of the men who enter the medical service of the mental hospitals has been raised to its present standard. To-day we have a large body of experts able to assist the profession generally in the problems that present themselves, but also engaging upon the researches whose outcome will be the psychiatry of the future. At the dinner of the Royal Medico Psychological Association Dr. GREIG SOUTAR drew attention to the fact that many of the teaching bodies now issue special diplomas in the subject of psychological medicine. This is a proof that while the public attention has been sharply focussed on the administrative side of lunacy, the educational authorities have largely combined to render fine and progressive scientific assistance.

THE NATURAL DURATION OF CANCER.

IN the course of the investigations of the Departmental Committee appointed in 1923 by the Minister of Health to consider available information with regard to the causation, prevalence, and treatment of cancer, certain difficulties have arisen. These are due to the fact that in the study of cancer from the clinical side there exists no well-defined criterion of the success or failure of a method of treatment. When a patient suffering from strangulated hernia has been relieved by surgical operation, he may clearly be said to be cured, since had the operation not been performed he would almost certainly have died within a few days; after its performance the patient, so far as his expectations of further life are concerned, is brought back into the category of the general population of the appropriate sex, age, and occupation. But it is less easy to interpret the word "cure" as applied to more chronic cases. For example, what is the criterion of cure in patients showing the classical symptoms of pulmonary tuberculosis? It would be too severe a test to demand that their average duration of life should be as long as that of a random sample of persons of the same age, sex, and occupation. These considerations have stimulated Dr. MAJOR GREENWOOD to make an attempt to find a basis from which inferences as

Manual of Surgery

By the late Alexis Thomson, M D, F R C S Edin and Eng, and Alexander Miles, M D, LL D, F R C S Edin Vol II, seventh edition Oxford Medical Press Pp 663 12*s*

The second volume of the manual deals chiefly with the locomotor apparatus, the brain, the spinal cord, and special organs. Fractures and dislocations are treated with great thoroughness, and on the rather unusual plan of discussing the injuries of each region separately. From the point of view of systematic description the method is a little confusing, but for purposes of diagnosis there is a certain advantage in describing under one heading all the injuries, for example, that can occur in the region of the shoulder The whole of this section is profusely illustrated, and the illustrations of deformities are extremely good The effects of injuries of the skull, and intracranial hæmorrhage, are admirably dealt with, but surely more than three pages might have been spared to the subject of cerebral tumours The volume contains an immense amount of information in a readily accessible form, and it is particularly well suited to the requirements of the student who wishes to look up information about cases he has seen in hospital. He could hardly find a more convenient volume to assist him in his studies

Bacterial Infection

With Special Reference to Dental Practice By J L T Appleton, Jun, B S, D D S, Professor of Microbiology and Bacteriopathology, the Thomas W Evans Museum and Dental Institute, School of Dentistry, University of Pennsylvania London Henry Kimpton 1926 Pp 474 28*s*

This stimulating text-book is intended to give dental students and practitioners a knowledge of the general process of infection and an understanding of the special bearings of this upon dental practice It is divided into three parts Part I treats of bacteriology, together with some very important information upon antiseptics and sterilisation, Part II of infection generally, and Part III of the special bacteriology of the regions dealt with by the dentist This stated arrangement is hardly adhered to, consequently the subject-matter is rather unsystematic, and there is a lot of overlapping between Parts I. and III The bacteriological descriptions assume that the reader already possesses a fairly comprehensive knowledge of the ordinary morphological and cultural characteristics of organisms, and there is a great deal of information included which has only theoretical importance Twenty pages are given up to a discussion of classification and two distinct systems are described In spite of an attempt to include too much, which results in the admission of matter which has only remote bearings upon the main theme, the book is nevertheless an illuminating one It sets forth information in a broad and sane way and may be read with profit by dental students and by those who have qualified, it certainly represents a level of instruction considerably higher than that which obtains in most of the dental schools in this country

Cancer Its Control and Prevention

By John F Hall-Edwards, late Senior Medical Officer in Charge of X Ray Department, Birmingham General Hospital Birmingham Cornish Brothers, Ltd 1926 Pp 88 2*s*

The object of this little book is to control and prevent cancer by educating the public The author impresses upon his readers that cancer is curable if recognised and treated in its early stage He describes the various symptoms which may be indicative of cancer in the different organs, and urges the public to seek medical advice without delay when there is any disturbance of health which might possibly be due to cancer. This part of the book, while it contains nothing new, is well and clearly written and can be recommended as sound advice But the statement on the cover that "the death-rate from cancer could be reduced within two years by 20 per cent if the public only knew and acted upon the advice given in this book" is not justifiable and is not justified by anything in the text The author merely repeats on p 27 that "it has been computed that 15-25 per cent of the deaths from cancer could be saved as the result of education by intensified propaganda" No explanation is given how this calculation is arrived at, unless it be the example given on p 41 Dr Hall Edwards refers there to the reports of the Radium Institute, where under the heading of "Moles, Warts, Papillomata," 74 cases have been reported as cured by treatment in two years He goes on to say "Taking these figures as they stand it is obvious that in two years 74 cases of skin cancer have been prevented"! The naiveté of this argument enables one to understand the author's confidence in the beneficial results of the intensified propaganda which he proposes In the United States a society for the control of cancer was founded in 1913, and has carried out an active propaganda for many years During that period the recorded mortality from cancer in the United States has considerably increased

Heredity

The Theory of the Gene By Thomas Hunt Morgan, Professor of Zoology in Columbia University New Haven Yale University Press 1926 With 156 figures Pp 343 18*s*

It was in 1825 that the Earl of Bridgewater, whose monument stands by Ashridge Park, left £8000 to the President of the Royal Society to get written a work "on the power, wisdom, and goodness of God as manifested in the creation", whence came Sir Charles Bell on the hand, Dr Roget on physiology, and the other famous Bridgewater Treatises In 1901 Yale University received a legacy of $80,000 in memory of Mrs Hepsa Ely Silliman, with which they were charged to procure and publish an annual course of lectures "designed to illustrate the presence and providence, the wisdom and goodness of God, as manifested in the natural and moral world" Prof Morgan's book is the nineteenth of a series, which includes Sherrington's Integrative Action of the Central Nervous System, Haldane's Respiration, Krogh's Anatomy and Physiology of Capillaries, and perhaps most significantly, Bateson's Problems of Genetics For in the dozen years which have gone by since Bateson stated his problems remarkable progress has been made towards their solution, as is shown by this admirable exposition of what Prof Morgan believes about the gene and why he believes it The theory of the gene states that the characters of an individual are referable to paired elements (genes) in the germinal material which are held together in groups and arranged in a linear order, that these pairs separate when germ-cells mature and recombine independently according to Mendel's laws, that there may be at times an interchange between the elements in corresponding groups The gene is a conception based on quantitative experiments and the theory says nothing about its anatomical representation, though there are many facts which make it likely that it is a particle of chromatin occupying a defined place in a series which makes up a chromosome Prof Morgan naturally puts his case strongly and, where it is possible, quite definitely, but the particular value of his book is that he faces his difficulties frankly, and those who have read only more popular accounts of modern genetics may be surprised to find that the simplicity and certainty of the matter are not quite as great as they had been led to think There is indeed a great deal of current confusion about genes and characters and the effects of environment and we can thoroughly recommend a careful study of this considered statement by a master to any serious student who wants to know the present position The diagrammatic illustrations are good hospital applied to particular people who, for one reason or another, are being treated in private, the functions of institutions for the reception of the last two classes of cases are obvious, but in considering institutions prepared to shelter patients requiring special observation and treatment the report may be called prophetic, inasmuch as, though such places are extremely needed, they are only just coming into existence All nursing homes may not fall neatly under this classification, if only because patients under two or three of the different classes may, of course, be found under one roof, but the category is a quite adequate one from which to consider the need for supervision, and of this need there seems to be no doubt in the public mind nor in the mind of the Committee The Ministry of Health was evidently alive to the great difficulty implied in the registration and inspection of maternity homes fulfilling functions in regard to public health and child welfare, for, in the recommendations, special exemption from supervision is provided for publicly controlled institutions, which cannot require the same sort of standardising that might be necessary for private adventures From the British Medical Association the Committee learned that that body would not object to the registration of nursing homes where the registration authority delegated its duties to a committee upon which both doctors and nurses would be represented, ensuring also that medical records and case sheets would not be open to lay inspection The complaints received by the Committee came from doctors—mainly directed to structural and sanitary defects in buildings, from nurses—mainly directed to inadequate accommodation for patients and staff, poor quality of diet, and inadequacy of staff, and from patients—confirming from their aspect the views of the nurses These complaints were considered by the Committee under the indicated headings of buildings, accommodation, staff, and treatment of patients, and in view of much publicity that has been given recently to the alleged neglect of patients in nursing homes, we would draw attention to one passage in the report "The Committee do not intend to criticise the work carried out by well-run nursing homes, for it is clear that in many cases the owners or managers of these homes are making the very best of structurally unsuitable buildings"

On such clear-cut issues as could be formulated, the Committee make concrete recommendations which will lead surely to "something being done" They find that legislation to secure registration and inspection of nursing homes should be introduced under the supervision of county and borough councils, with power of delegation to a committee upon which doctors and nurses are represented, the inspection to be carried out by the medical officers of health with technical assistance, the inspection, they hold, should be limited to general questions and should not embrace any inquiry into medical records or the private affairs of patients They hold that the term "nursing home" should include all types of home—that is to say, maternity homes also—but not any publicly controlled institutions Charitable organisations, they say, could be exempted by action of the supervising authority for definite periods, but they do not agree that a nursing home should go free of inspection on the grounds of the residence or the control of a medical practitioner They recommend that appeals against refusal or cancellation of registration should be made to a referee appointed by the Minister of Health, and that all homes, including maternity homes, should be brought under one comprehensive scheme Action should follow on this report

Annotations.

"Ne quid nimis"

INTERNATIONAL RED CROSS CONFERENCE ON THE WELFARE OF THE SEAMAN

BETWEEN June 28th and July 5th an itinerant conference was held in Oslo Bergen, and Trondhjem with the object of uniting the Red Cross Societies of the world in a movement for bettering the health of the sailor The British representatives were Mr L Bowden, Dr Butler (of the International Labour Office), Surgeon-Commander L F. Cope, R N, Colonel L W Harrison, Dr C Lillingston, Dr F N Kay Menzies, Mrs Neville Rolfe, Dr Norman White, and Mr Murray-Williams The aim of the conference, which was organised by the Norwegian Red Cross Society and the League of Red Cross Societies, was to bring together the representatives of the national Red Cross Societies of the maritime countries of the world and certain other organisations such as the International Labour Office, to study the measures already taken in Norway for the welfare of the seaman, and to confer over steps to be taken in the future for his welfare Of the many items on the agenda, which included the international standardisation of a medicine chest and medical manual for ships not carrying a doctor, that which elicited the most lively discussion was the plan devised by Dr Harald Engelsen, of the Norwegian Red Cross, for a network of medical stations under the Red Cross for seamen in every port It was his original intention that the Red Cross should choose one doctor in every port to act as the agent of the Red Cross, putting his surgery at the service of the sick seaman, who would pay the ordinary doctor's charges and who would, if he required specialised treatment, be passed on to a specialist or a hospital where he could receive such treatment It was argued by Dr Engelsen in favour of this scheme that the seaman would benefit by having a doctor found for him and guaranteed by the national Red Cross Society of the country; also that the patient would have the advantage of continuity of treatment as he travelled from one country to another in the charge, so to speak, of Red Cross doctors who would be more or less in touch with each other, information as to diagnosis and treatment being carried by the patient from one doctor to another The Secretary-General of the Norwegian Medical Association (Dr. Jörgen Berner), gave the blessing of his Association to this suggestion, although it entailed granting a monopoly to only one doctor in each port The attitude of the foreign delegates to the scheme might be described as one of frank, but friendly, criticism They were agreed as to the desirability of linking up the welfare work for seamen under one single international organisation, such as the League of Red Cross Societies, but they did not see how the Norwegian scheme in its entirety could be accepted by every other maritime country. The first three resolutions, unanimously adopted by the conference, gave expression to this feeling They were

1 That bureaux for furthering the health and general welfare of seamen be established in seaports throughout the world in close liaison with, and as a further development of, such national and international action in this field as has already been taken

2 That each bureau be placed in a prominent position at the water-side The chief function of these bureaux would be to furnish (*a*) treatment or information as to where appropriate medical advice and treatment can be secured, (*b*) postal facilities such as addresses to which the seaman's letters might be sent, and (*c*) information as to the local recreational and social facilities and sleeping accommodation

3 That such seamen's bureaux should be distinguished by a common badge of world-wide application.

To assure continuity of future action, the conference adopted as a further resolution, that—

"The League of Red Cross Societies should invite the International Labour Office, the Health Organisation of the to the value of treatment in cancer may ultimately be drawn In an introductory paragraph to a report on the Natural Duration of Cancer,[1] he deprecates the use of the word "cure" without qualification in assessing the results of treatment of any chronic disease, and suggests that a numerical measure of cure must take account of three quantities (1) the average duration of life of a person, of the same age as the patient, not known to be suffering from the disease, (2) the average duration of life of a person suffering from the disease and left untreated, (3) the average duration of life of a person suffering from the disease and treated in the manner the value of which it is desired to test Of these quantities, one only, the average duration of life from any age in the general population, is known at all accurately The duration of life after treatment is known, but only to a rough approximation, for certain forms of cancer To collect information on the "natural" duration of life of cancer patients is the object of this report It is admitted that *really* accurate knowledge of the average length of life of a cancerous process not radically treated can never be had because its onset is often insidious There are some forms of cancer—for instance, cancer of the stomach—where the earliest indications of disease are almost wholly subjective But there are other forms, cancer of the breast or of the tongue, for instance, where something tangible, a lump or a sore, is given, and in these our measure of duration, still only rough of course, still probably understated, is of real value Dr **GREENWOOD** believes that it is worth while to seek measures of natural duration at least for cancers of tongue, breast, cervix uteri, rectum, and œsophagus

The data here analysed were obtained by the courtesy of several hospital staffs and include 4238 cases relating to seven primary sites From records made by Prof W S **LAZARUS-BARLOW** (London), Sir **GEORGE BEATSON** (Glasgow), Dr S **WYARD** (London), Dr **POWELL WHITE** (Manchester), and Mr **CARTER BRAINE** (London) he finds the mean duration in months to be 38 3, 20 9, 26 7, 16 5, 12 0, 14 5, 16 8 respectively in cancer of the breast, uterus, rectum, tongue and mouth œsophagus, larynx, and stomach There is no significant difference between the different sets of averages obtained Dr **GREENWOOD** finds no confirmation of the general opinion of clinicians that age at onset is an important factor There seems to be little relation between age of onset and duration The ordinary arithmetic average duration, however, puts the case in too favourable a light, since the existence of a small number of persons who survived a very long time—for example, two breast cases and one rectal case lived over 30 years—has pulled up the arithmetic average The mean and the median value —i e, the value midway between the longest and shortest durations—are often far apart While the actual arithmetic average duration of cancer of the breast is over three years, half the patients are dead within a little more than two years and three months, 25 per cent do not live more than 18 months, and only 25 per cent survive beyond four years one month For cancer of the rectum the difference is less striking, the arithmetic mean duration is only three months longer than the median value

The significance of the results from the statistical point of view is discussed in some detail From the material at his disposal Dr **GREENWOOD** has constructed a survivorship table, calculating the chances of survival from nought to six years after onset of cancer in each region in untreated cases Taking cancer of the breast as an example, he shows how from the data of natural duration an attempt to measure the effects of treatment may be made He is careful to point out that in the present state of our knowledge a certain element of conjecture is involved, and that certain assumptions are inevitable Accepting these assumptions we have the following summary results The normal expectation of life of a woman aged 55 is 18 87 years, the expectation of life of a woman with untreated cancer of the breast is 3 25 years, the expectation of life of a woman operated on under "average" conditions is 5 74 years, and of a woman operated on under the best conditions is 12 93 years To-day the annual quota of new cases of cancer of the breast in England and Wales is probably at least 5000 Not more than half the patients undergo the radical operation and of these fewer than half again are operated on under the most favourable conditions How many years of life will these 5000 women, on the average, enjoy? 2500 of them will have 3 25 years apiece, 1250 will have 5 74 apiece, 1250 12 93 years each The grand total is 31,462 5 years Had each enjoyed the normal expectation, the total would have been 5000 multiplied by 18 87 or 94,350 years If all had been operated on under the most favourable conditions, the quota of years would have been 64,650, more than 30,000 years of life beyond what they may actually expect Sir **GEORGE NEWMAN** emphasises in a prefatory note the advantage enjoyed by those who submit to early operation in this form of cancer Recent records of cases of women operated upon for undoubted cancer of the breast in various provincial cities, notably Leeds,[2] confirm Dr. **GREENWOOD's** arresting conjecture that resort to early operation in cancer of the breast would, in the aggregate, add thousands of years to the active life of the nation

NURSING HOMES

A Select Committee, appointed by the House of Commons on March 2nd last to consider and inquire into the question of the inspection and supervision of nursing homes, and to report what legislation, if any, is necessary or desirable, have issued this week a well-considered and prompt report[3] Evidence was taken not only from medical and nursing associations, but from many engaged with the administration of public health in urban and rural districts, private medical practitioners, matrons and proprietors of nursing homes, and such persons with direct experience as nurses, patients, or visitors The information from the witnesses was sought in reply to the two questions, whether the general conditions under which nursing homes are conducted render their supervision by a public body advisable, and, if so, how such supervision can be most effectively obtained and exercised

The difficulty of defining the institutions to be considered was met by a classification under which all nursing homes were placed in five classes, accordingly as they provided accommodation for medical and surgical cases, for maternity cases, for cases requiring special observation and treatment, for senile and chronic cases, and for convalescent cases It will be seen that under the first two headings we have the usual material of the general or special tained pigment present in the cytoplasm but not in the nucleus. The larger cysts for the most part had no epithelial lining and the contents were in close apposition with the surrounding connective tissue. The pigment was very abundant and gave a blue-black appearance to the central part of the tumour. It contained no iron and was regarded as melanin by the authors, who believe that this case is the first on record in which melanin has been found in an odontome. Considered as an epithelial odontome the growth has other interesting features. The view that these tumours arise from an abnormal development of the enamel organ is supported by its structure. The authors advance convincing arguments in support of their suggestion that the growth may have arisen as an aberration of the enamel organ of the missing permanent incisor. Whatever its origin it is peculiar in its situation, since most tumours of this nature occur in the mandible, and in the small resulting disturbance of tooth development.

THE EX-BABY

THE discussion on child welfare which took place at Westminster and was reported in THE LANCET of July 17th drew attention to a gap in our organisation for the care of the child. Antenatal and baby clinics provide for help and direction in regard to health up to the time of weaning, but Dame Janet Campbell showed that the "ex-baby" lacks systematised care until school life begins, when the school clinics take up their share in preventive medicine. The good work already done has probably been reflected in improved conditions of children who are not subject to supervision, but we cannot let this probability satisfy us, and the hiatus between babyhood and school age must be bridged. The gap in organisation has a noteworthy linguistic correlate, for Dame Janet Campbell's use of the phrase "ex-baby" is justified by the absence of a current word to specify the infant who is no longer "the baby" and has not yet attained the status of a school child. Yet during this period are being laid the foundations of the individual's character and disposition, upon which will depend his actions and reactions, and, to a great extent, his future happiness and even bodily health. There is a saying, attributed in varying forms to various people, but generally put into the mouth of an eminent theologian, who is credited with declaring that if he could direct the training of a child up to the age of seven he cared not a bit who trained it afterwards. Modern study of the development of character traits, however, leads us to attach more importance to the influence of the family, often unwittingly exercised, than to deliberate efforts to instruct. From these observations it is only a step to the view of Freud that, whatever may be its exciting cause, the foundations of a psycho-neurosis are laid in the first five years of life. Inborn temperament plays a part, but those neurotic reactions in the nature of fear, jealousy, hatred, and the like, which appear so irrational to the observer and yet are subjectively self-sufficient, are but repetitions of childish emotional behaviour. We are so accustomed to our loss of memory for the period when our own reaction modes were being laid down that we overlook the mystery of it. We say we were too young to remember. But any mother can give examples of the wonderful memory of her ex-baby, and the conclusion seems reasonable that we forget because we are too old to remember. According to the psycho-analytic view we forget, or repress, because the period is a time of conflict between primitive wishes and the growing inhibitions against them. Certainly the child who has "his nose put out of joint" by the coming of a "little stranger" will probably never know if a feeling of neglect then experienced was the first of a train of reactions culminating in a general tendency to undue resentment at any rebuff. The only child—who is often a nervous child—may never pass satisfactorily through the stage of dependence upon the parents, and the success of Barrie's best-known play may indicate that the memory of that stage of dependence still attracts both grown-ups and those who have not long passed through the ex-baby phase. Few of us would easily admit that the happenings of that phase had any influence upon our appreciation of Peter Pan. These speculations may appear remote from the subject of the provision of children's clinics, but preventive medicine has a task before it in the "plague of nerves" that interferes with the happiness and efficiency of so many people. If the ex-baby age is that in which are established not only character and disposition, but also the possibilities of later neurotic troubles, then the emotional situation of the child must be studied in conjunction with the purely physical side.

THE TOXICITY OF ZINC

THE use of zinc as a protective coating for galvanised pipes and cooking vessels, in cosmetics and medicinally, lends interest to the question whether this metal possesses toxic properties. The acute reaction known as brass-founders' ague or spelter chills, due to exposure to vapour of the metal at high temperatures, may be disregarded as resulting from an unusual physiochemical state; but even here chronic manifestations following frequent attacks have not been described. The subject has been approached in two recent articles in both of which literature bearing on it is summarised, but the conclusions drawn are unusually diverse. One of these articles considers the position of workers in galvanising plants[1] exposed to fumes of zinc sulphate and zinc chloride, here the authors report widespread gastro-intestinal conditions, varying from gastro-enteritis in the younger workers to gastric and duodenal ulcers in older men. A period of from 5 to 20 years is thought necessary for the production of these lesions. The experimental work of others is claimed in support of zinc being the causative agent. No such train of events, however, has been described in this country, on the contrary, in one district where galvanising is the staple industry, gastric ulcers, although not uncommon among domestic servants, have been noted not to occur among the factory women.

The second article referred to[2] gives the evidence for considering zinc to be universally present in animal tissues, and present in remarkably similar total concentrations in animals of different species and in approximately constant concentrations in different animals of the same species. The authors deduce from the facts that this metal, instead of being a poison, takes part in normal metabolism of plants and animals. Corn deprived of zinc becomes chlorotic, it acts as a catalytic fertiliser for maize. Animals on a zinc-free diet do not flourish; the zinc content of yolk of egg, milk, and spermatic fluid is high. An understanding of the normal occurence and rôle of zinc is needed when evaluating the effects of abnormal amounts introduced in the course of exposure to industrial processes. The suggestion is certainly new that zinc promotes the efficiency of growth processes.

THE NORMAL BLOOD COUNT

IF asked the normal number of red cells per c mm in the human being, nine out of ten medical men—students or practitioners—would reply, five million. A few, perhaps, would qualify their answer by saying that in the female the count is lower by about 500,000. The universal acceptance of this standard is something of a mystery, but the figure, repeated in text-book after text-book, is the basis for calculating the colour-index. The whole subject of the normal standards for the blood has lately been carefully reinvestigated by E. Osgood,[3] working in Portland, Oregon, and his results are worthy of close consideration. Taking samples from healthy male medical

League of Nations and other international organisations concerned to coöperate in appointing a standing committee on the welfare of seamen, this committee to arrange for expert investigation of (*a*) facilities for the medical treatment of seamen (e g , standardisation of ships' medicine chests, medical manual, a wireless code for medical consultations at sea, education of ships' officers in first aid and in the use of medicine chests, health propaganda among seamen, &c), (*b*) welfare conditions on board and in port, the provision of recreational facilities for seamen of all nationalities, social conditions in the ports, ships' libraries, films, &c "

It was the general opinion of the delegates to the conference that it had brought to light an important gap in the welfare work for the seaman, and that the Norwegian Red Cross Society, by inviting the sister societies to confer on this matter, had started an international movement which promised radical reforms.

SMALL-POX IN RELATION TO CLIMATIC CHANGES.

Data for epidemiological studies in tropical countries are not always easy to obtain, India is exceptional in possessing meteorological records and statistics of the incidence of various diseases extending over some 50 years After prolonged study of this material, of which he is in a position to detect the limitations as well as the significance, Sir Leonard Rogers has arrived at definite conclusions as to the influence of climatic conditions on the incidence of leprosy, tuberculosis, and pneumonia More recently he has drawn attention, in a paper read before the Tropical Diseases Section of the Royal Society of Medicine, to the relation between absolute humidity and small-pox prevalence in India He has now expanded this communication into a report[1] to the Medical Research Council, presenting tables, charts, and diagrams which give support to his view that by careful study of climatic conditions in India it is possible to forecast epidemics of small-pox He finds that the small-pox incidence in India is greatest and most uniform from year to year in Madras, the only province not receiving much rain during the south-west monsoon months from June to October In all the seven provinces receiving the south-west monsoon rains there is a remarkable decline of small-pox every year at that season, followed by an increase during the ensuing cold and hot dry seasons, once more checked by the next monsoon Rainfall alone does not explain this great fall of small-pox during the south-west monsoon The provincial average small-pox incidence shows no relation to the monthly temperature, and none to the relative humidity in the damp areas of Lower Bengal, Assam, and Madras The absolute humidity (that is, the amount of aqueous vapour as measured by its pressure, a convenient measure of combined humidity and temperature) shows a close relation to small-pox prevalence It rises to its maximum with the annual decline of small-pox during the south-west monsoon in every province receiving its main rain then In Madras both the absolute humidity and the small-pox rate are stationary at that season in the absence of the south-west monsoon, while the maximum absolute humidity occurs as early as April and May and is accompanied by the annual moderate early decline of small-pox The early winter north-east monsoon rains occur during a fall of the mean monthly temperature and of the absolute humidity, thus explaining their failure to prevent the winter increase of small-pox in Madras Sir Leonard Rogers holds that the influence of high absolute humidity in checking small-pox suffices to explain the seasonal prevalence of the disease in all parts of India In the less rainy areas of the North-West and Central India, with average absolute humidity during the monsoon of about 0 700–0 800, low absolute humidity during that period is nearly always followed by excess of small-pox in the ensuing dry seasons, while in the areas with heavy rainfall of Bengal and Assam, as well as in Madras, the absolute humidity during the summer, which is very high, reaching 0 800–0 970, has very little relation to small pox incidence However, years in which the humidity is low in the autumn, when normally it ranges from about 0 700 to 0 800, are generally followed by excess of small-pox in the ensuing dry months The only exceptions are that low humidity soon after a small pox epidemic, which has exhausted most of the susceptible material, may not result in any increase of the disease, while five or six consecutive years of normal or high absolute humidity may be followed by a rise of small-pox, on account of the accumulation of susceptible persons Sir Leonard Rogers believes that by watching the absolute humidity in India, and possibly in other tropical continental countries, at the season when they normally average about 0 700–0 800, about four-fifths of small-pox epidemics may be foreseen two or three months ahead, in time to enable the public health authorities to issue warnings and to organise additional vaccination staff to cope with and minimise the approaching outbreak of small-pox

A MELANOTIC EPITHELIAL ODONTOME.

The occurrence of a melanotic epithelial odontome in a child of 5½ months has recently been recorded by Mr J Howard Mummery and Mr A T Pitts.[1] According to the mother a swelling had first appeared in the front of the maxilla at about one month and had steadily increased in size, at the time of examination it was about the size of a small walnut, and was situated on the anterior aspect of the maxilla in the incisor region, chiefly on the right side The mucous membrane was stretched over the hard tumour but was freely movable A radiogram showed that the tumour cast a shadow much less dense than that of bone A dense patch, evidently calcified, on the left side resembled the imperfectly formed crown of a tooth There was no sign of the outer alveolar plate in the radiogram At operation a flap of the stretched mucous membrane was raised over the tumour and it was found that the outer alveolar plate had been thinned to the consistency of tissue paper over the growth but was still complete This bone was removed as well as the thicker bone over the lateral margin of the tumour, so as to give access to the growth, which was adherent to subjacent tissues only on its deep aspect Here it was intimately united to the bone, spicules of which passed into its substance, and some force was needed to dislodge the tumour The cavity was obliterated to some extent by crushing in the expanded bone, and the flap of mucous membrane was sutured into position with catgut. Recovery was uneventful and four years afterwards the only abnormalities were a twisted right lateral incisor and the absence of the right upper central incisor, all the other deciduous teeth being present. The concavity of the anterior surface of the bone above the missing tooth suggested the absence of the permanent right central incisor, and radiograms confirmed this There has been no sign of local recurrence or metastasis On examination the tumour proved to be a complex one It contained calcified bodies, a mass of imperfectly formed enamel, and long columns of enamel organ arranged in layers A narrow epithelial band was seen at the margin with numerous buds of epithelium extending into the growth, bearing a striking resemblance to a tooth-band with young tooth-buds growing from it Portions of dental pulp were also seen, as well as some imperfectly formed dentine The histology of the soft part of the tumour showed the typical structure of an epithelial odontone or multilocular cyst The smaller cysts were surrounded by epithelial cells, which appeared quite black from the con-

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CLXXXII

THE TREATMENT OF URINARY CALCULUS

Cutting for stone is an operation of such antiquity and has received so much attention in lay and medical writings that it occupies a somewhat disproportionate prominence in the minds of those who only occasionally see a case of urinary calculus It will be convenient, therefore, to commence by discussing these cases of stone in which operation is unnecessary or is contra-indicated It is presumed that in stones of the kidney or ureter an X ray film of good quality has demonstrated the calculus, and in stones in the bladder that this viscus has been examined with the cystoscope Operation is contra-indicated in large bilateral renal stones In such cases the destruction of kidney tissue is very considerable, and what is left may be little more than sufficient to carry on the renal function An operation for the removal of a large branched calculus entails extensive destruction of renal tissue, and may be followed immediately or after an interval by failure of the renal function Further, it is practically certain that within a few months or at most a year or two the stones will have re-formed Operation in such cases is only performed where there is severe pain, septic absorption, or obstruction leading to hydronephrosis or pyonephrosis, all of which are rare in this type of calculus Where there are stones in both kidneys, one kidney being occupied by a large mass of stones and the other being the seat of a small calculus, the small stone should be removed by operation without delay. Such a stone, if impacted in the ureter, is likely to cause calculus anuria, and it is easily removed by pyelolithotomy without destruction of the tissue of the healthy kidney The treatment of the extensively diseased second kidney will vary in individual cases, but my inclination would be to leave the kidney alone if it were giving rise to no symptoms When the calculi in each kidney are of moderate size and too large to pass down the ureter, they should be removed by operation A cutting operation is rarely required in small stones in the kidney or ureter In stones up to the size of a pea or even larger, where the stone is rounded or shaped like a date-stone, it may pass by the natural channels At the present time, when early diagnosis by means of the X rays is the rule, these comprise about 80 per cent of the cases of stone in the kidney and ureter The small stone that is obvious may so far be the only one formed, or small stones may be formed and passed at frequent intervals One of the chief arguments against operation in such cases is that the operation does not confer immunity from further stone formation Recurrence in the future is rather more probable than non-recurrence and operation should, other things being equal, be avoided

Medical Measures

The treatment in such cases consists in powerful diuresis, supplemented if necessary, by the passage of ureteral bougies Diuresis is best produced by means of one of the natural diuretic waters, such as Contrexéville, Vichy, or Vittel, or a visit may be paid to one of these spas

The method I usually adopt is based upon that in use at the spas A bottle of the water is taken before breakfast each morning for a month One hour before breakfast the patient drinks one-third of the contents of a litre bottle and then takes exercise, preferably walking, for a quarter of an hour Another third is then taken and followed by a similar period of exercise, and then the final third, with a subsequent period of exercise and a rest before the first meal During the rest of the day the patient carries on his ordinary routine, exercise being encouraged After a month of this treatment, a rest is given from the forced diuresis for a fortnight, and then a second course is started Repeated diuretic courses are given with intervals for a year or more A course of treatment at one of the spas mentioned lasts three or four weeks, and the spas are open from early May to late September

Measures to Facilitate the Passing of the Stone

Should the stone have failed to pass under the diuretic treatment, its discharge may be assisted by dilatation of the ureter and by other means For this purpose the operating cystoscope, a large catheterising cystoscope, is used Ureteral bougies of large size are passed up the ureter These serve to dilate the lumen of the duct and also to move the calculus which may have become arrested in its passage down the ureter by a small fold of mucous membrane The injection of novocaine through the ureteral catheter to relieve spasm of the ureteral muscle, and of sterile paraffin to facilitate the descent of the stone, may be tried The vesical orifice of the ureter is the narrowest part of the duct, and this may be incised by fine scissors passed through the operating cystoscope Where the calculus lies at the ureteric orifice, partly projecting into the bladder, further assistance may be obtained by burning the edge of the orifice with the high-frequency cautery, and the stone may be moved by means of fine forceps Where the stone lies near the bladder, bimanual massage of the lower ureter by means of the finger in the rectum or vagina, and the second hand above the pubes, should be tried These methods are of value where the stone lies at the brim of the pelvis or in the pelvic segment of the ureter They are used in combination with, or followed by, the diuretic treatment The discharge of the calculus is facilitated by their use, but the patient should be warned that there is no absolute certainty that the stone will come away, and that no definite time for its discharge can be given It is a matter open to discussion as to how long a stone may safely be allowed to remain in the ureter or renal pelvis

If pain and hæmaturia have been excited by exercise, and the patient's activity is being seriously curtailed, or his business interfered with, and the non-operative methods have failed, it is better after waiting six months or a year to remove the calculus by a cutting operation than to leave it If, on the other hand, the stone is causing only slight symptoms there will be disinclination on the part of the patient to have any operation done It must, however, be remembered that the stone will increase in size and complications will arise that change for the worse the prognosis for cure after operation, and on this account operation should not be delayed indefinitely.

Operations for Stones in Kidney and Ureter

There are certain indications for the removal by cutting operation of a small calculus in the kidney or ureter—namely, urinary infection, dilatation of the renal pelvis, and anuria Dilatation is diagnosed in the early stage, before extensive destruction of the kidney has taken place, by means of pyelography A calculus of the kidney or ureter which is unsuitable for treatment by diuretic or manipulative methods should be removed by cutting operation Before carrying this out it is necessary to obtain information in regard to the second kidney. The two most common dangers in regard to the second kidney are the occurrence of stone in this kidney also and impairment of the renal function by sepsis A complete X ray examination of both kidneys and ureters and the bladder should therefore be made in every case of urinary calculus A specimen of the urine of the second kidney should be obtained by passing a ureteral catheter, and examined by estimating the percentage of urea and cultures made from the bacteria

Pyelolithotomy—The removal of a stone from the kidney should, if possible, be carried out by an students this worker found that the normal red cell count ranged from 4,400,000 to 6,390,000 per c.mm., with an average of 5,390,000. Counts of more than 6,000,000 occurred six times in the series of 153 subjects, and this finding ought to discourage the custom of reporting all cases with blood counts of more than 6,000,000 as polycythæmia. On investigating the normal standard of hæmoglobin Osgood found even greater confusion. Unfortunately, the vast majority of those who, using their own particular method, report a percentage of hæmoglobin, never stop to inquire on what standard that percentage is calculated. The methods most commonly used in this country are probably those of Haldane, Dare, and Tallqvist. These all take 13.8 g. of hæmoglobin per 100 c.cm. as the normal; but the standard for the Newcomer method, on the other hand, is 16.92 g. per cent. Osgood found an average of 15.76 g. per cent. with extreme variations of 13.44 to 19.03. Since the usual standards of hæmoglobin adopted in this country, and the assumed normal of five millions per c.mm. for the red cells, are (according to these observations) both too low, it follows that the normal colour-index, usually taken as somewhere in the neighbourhood of 0.85, is also too low. Osgood found the average colour-index to be 1.00, with variation between 0.84 and 1.21. Very great importance has been attached, and undoubtedly must attach, to the colour-index in the diagnosis of pernicious anæmia. But the results reported above go to show that its significance is very variable in blood counts performed in the ordinary way. "It is necessary," Osgood says, "to convert all hæmoglobin estimations into terms of grammes per 100 c.cm. before calculating colour-indexes, and it would be desirable to have all hæmoglobinometers standardised to read in grammes per 100 c.cm." This conclusion obviously demands the attention of all hæmatologists, whether laboratory workers or clinicians.

THE ACTIVE SUBSTANCE OF THE THYROID GLAND

ONE of the most interesting communications made in connexion with the joint meeting of the Biochemical Society and the London Section of Chemical Industry, which we report on p. 199 of our present issue, was that of Prof. G. Barger, professor of chemistry in relation to medicine in the University of Edinburgh. In the absence abroad of Dr. C. R. Harington he discussed the progress of the work on the chemistry of the active substance of the thyroid gland since its isolation by Prof. E. C. Kendall in 1919. Prof. Kendall obtained from the gland a crystalline substance, containing 65 per cent. of iodine, which was shown to be the factor through which the thyroid exerts its control over the metabolic rate. The method of extraction was laborious and the yield so poor that for commercial purposes it was essential that a simpler and cheaper method should be devised. Quite recently Dr. Harington, working in the Department of Pathological Chemistry of University College Hospital, has succeeded in obtaining a far better yield. He gave an account of his experiments in the *Biochemical Journal* (vol. xx., p. 300), acknowledging the helpful advice received from Prof. Barger throughout the progress of the investigation. Having noticed certain discrepancies in Kendall's work, Dr. Harington sought to improve on his methods. Prof. Kendall had only succeeded in obtaining a total yield of 33 g. of thyroxine from three tons of fresh thyroid gland. It appeared probable that a considerable proportion of the total loss of active material occurred during the preliminary process of hydrolysis of the gland in sodium hydroxide, so that the first attempts were directed towards finding a substitute for this process. After several experiments, Dr. Harington found that hydrolysis with barium hydroxide appeared to promise more favourable results. Full details are given of his method, which gave an average yield of 0.12 per cent. of thyroxine from the dried gland and 0.027 per cent. from the fresh gland. Having arrived at a practicable method for the preparation of comparatively large quantities of thyroxine, Dr. Harington proceeded to reinvestigate the chemical constitution of the substance. After deciding upon a method for the removal of the iodine from the thyroxine he describes at some length his experiments in the degradation and synthesis of this desiodo-thyroxine, of which the formula is set out in our brief report of Prof. Barger's observations.

Up to the present the orientation of the iodine atoms has not been determined, but experiments indicate that they probably occupy 3, 5, 3′, 5′ positions. The comparison of the physiological action of thyroxine and desiodo-thyroxine will doubtless be undertaken shortly and can hardly fail to lead to considerable advance in our knowledge of the pathological processes at work in the various forms of goitre.

THE LONDON POST-GRADUATE HOSTEL.

THE opening meeting of the Post-Graduate Hostel will be held at the Imperial Hotel, Russell-square, on Monday, July 26th, at 7 P.M., when officers will be elected and rules approved. The objects of the hostel are to welcome medical visitors who come to London, to promote an interchange of ideas by means of conversation and informal addresses, and to supplement and encourage the work of the Fellowship of Medicine and other bodies which arrange for post graduate instruction. A smoking-room and a reading room have been set aside at the hotel for residents and visitors, and the rules for their use, which are being proposed, are as simple as possible. It is suggested that the privileges of the hostel shall be restricted to fully qualified medical practitioners, that any such practitioner shall be allowed to dine with the members at the ordinary hotel charges on presenting his card; that a register of attendances and a register of discussions shall be kept; and that informal discussions shall be held from time to time at 9 o'clock in the evening on subjects previously announced in the medical journals. After the business meeting on Monday next there will be a reception at 7.30 P.M., followed by dinner at 8 P.M. At 9.15 P.M. Dr. Alfred Cox will take the chair at an address by Sir D'Arcy Power on the Hostel and its Objects. It is hoped that as many as possible will attend to hear the address even if they cannot dine at the hotel. Ladies and friends of medical men will be cordially welcome. Those who intend to dine on this occasion are asked to inform the management of the hotel in good time. Wide support should be obtained for this attempt to provide a rendezvous for medical men from abroad.

The discussion for Friday, July 30th, will be on the Difference between Inflammation and Hyperplasia, and will be opened by Sir Lenthal Cheatle.

THE Registrar-General's "Statistical Review of England and Wales for 1924" was published this week (New Annual Series, 4) at the price of 5s. net from the Stationery Office.

INDEX TO "THE LANCET," VOL. I., 1926.

THE Index and Title-page to Vol. I., 1926, which was completed with the issue of June 26th, will shortly be published. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

forming Sections of Venereal Diseases and of Radiology at the meeting to be held in Edinburgh in 1927.

Financial Position

The Treasurer, Mr Bishop Harman, in moving the adoption of the annual report under "Finance," said there was a balance in hand of £783 6*s* 4*d*. The balance of £8000 last year had been swallowed up by non-recurring expenses such as the equipment of the new building and the demands of the Scottish House. There was now no loan nor overdraft at the bank. There had been during the last few years a steadily progressive increase both in the income and in the expenditure due to the great increase in membership. An increase of £2600 in the general expenses account was due to the delegations to America and South Africa and legal expenses incident to the lease of the new house.

Funds for Research.

Dr F C Martley spoke of the importance of spending more money on pure science, since the first object of the Association was the advancement of science. Apart from exceptional years, such as the one just concluded, an average profit of £6000 might be looked for, and it was scandalous to spend only £1000 on research. Dr J W Bone pointed out that much of the general expenditure of the Association was for scientific purposes in connexion with the *Journal* and with the work of many of the committees, such as that on the causation of puerperal morbidity and mortality. It was not just to regard the money set aside for research grants as all that was devoted to science. Dr E B Turner pleaded for more money for research work. The *Journal* nearly paid for itself and the money used to finance it could not be regarded as an expenditure on science. There was also scope for many more British Medical Association lectures. Dr D Lawson said that £10 000 a year would be a suitable sum to spend on science, and suggested raising the money by an increase in the subscription.

Remuneration of Laboratory and Research Workers

The scale of salaries laid before the Representative Body last year was passed as the established policy of the Association. This scale states :—

(*a*) That whole-time (1) non-professional medical teachers, and (2) medically qualified laboratory or research workers should be grouped into three grades as defined below, and with the salaries as stated :—

Grade III.—Comprising those who are junior workers temporarily employed on probation; no person shall remain in Grade III for more than three years.

That the minimum salaries for Grade III shall be as follows: 1st year, £300; 2nd year, £350; 3rd year, £500.

Grade II.—Comprising laboratory or research workers or teachers who have had three years' experience in Grade III or in work of a similar character, and who are permanently and exclusively employed as such. That the minimum commencing salary for Grade II shall be £600 per annum.

Grade I.—Comprising those of Grade II whose qualifications or duties justify a position of seniority in status and a higher remuneration. That the minimum salary for Grade I shall be £750 per annum. That after the probationary period (i.e. Grade III) has been completed, dismissal should be possible only on grounds of neglect of duty, improper conduct, or incapacity.

(*b*) That non-professional medical teachers and medically qualified laboratory or research workers holding part-time appointments should receive remuneration for the time engaged, at the rate of not less than £600 per annum.

Amendments by the St Pancras division and the Dundee branch, seeking to exempt from this scale posts where there were special scientific or other advantages outweighing the financial, and small hospitals or schools where the drain would be serious, were rejected, the Chairman of Council and the Chairman of the Science Committee strongly urging the members not to weaken the policy of the Association in any such way. Sir Robert Bolam said that the Council's duty was to execute the policy of the Representative Body with discretion and any case of real hardship would be sure of sympathetic consideration.

Present Strength of the Association

The Chairman of the Organisation Committee announced that the membership of the Association had now reached 31,600, an increase of 2000 on last year and of 25 per cent. during the last three years. He referred to the success of the Handbook for the Newly Qualified, a new edition of which had recently been brought out. Three new divisions had been organised during the year. The Australian branch was doing well, and in Canada there had been very gratifying results of the affiliation carried through last year. It was hoped to do something in the near future to improve the position of the medical profession in India.

Locum Bureaux

The recommendation from the Bath meeting, authorising the establishment of Locum Bureaux under B.M.A. auspices, had been investigated, but it had been found that such bureaux would be unremunerative for a very long time and would necessitate considerable expense. Their establishment had, therefore, been given up in favour of an agreement with an existing organisation, which would obviate any technical or legal difficulties.

The Medical Profession in South Africa

Dr Morton Mackenzie sketched briefly the difficulties encountered in South Africa, where until recently two separate associations had existed, the British Medical Association and the South African Medical Association. The consistent policy of the Council had been to seek for the unity of the profession and as the result of an organising tour by Dr A. Cox amalgamation of these two bodies had been secured. Dr K B Alexander of East London, Dr. H W Dyke of the Orange Free State, Prof. J. W. C Gunn of Cape Colony, and Dr. E A. Seale of the Cape of Good Hope all spoke of the high appreciation in South Africa of Dr Cox's services. Motions were passed welcoming the amalgamation, congratulating the leading members of both the South African medical bodies on the statesmanship shown, and wishing the new Medical Association of South Africa (British Medical Association) every success.

The Science Committee

Dr C O Hawthorne, Chairman of the Science Committee, in proposing the adoption of the remainder of the annual report under the heading "Science," remarked on the increasing number of applications for scholarships and grants in aid of research, to the important work carried out by scholars and grantees, to the investigation into the Spahlinger treatment, and to the Sir Charles Hastings clinical prize for general practitioners. The 1926 prize had been awarded to Dr Norman Porritt of Llandudno, for a study entitled the Abdomen in Labour. A high level of excellence was reached in the 20 clinical studies submitted. The report on rheumatic affections in childhood would doubtless prove the starting point of new enterprise, investigation, and research.

During the course of the day the following ten members of Council were returned unopposed: Dr G B Hillman (Wakefield, Pontefract and Castleford), Dr I W. Johnson (Bury), Dr D G Greenfield (Northamptonshire), Dr. A W. Nuthall (Birmingham), Dr E B Turner (London), Dr. W. Paterson (London), Dr H C Bristowe (Bristol), Dr A Lundon (Guildford), Dr. C E. Douglas (Fife), Dr J G McCutcheon (Glasgow), and Dr J. Mills (Connaught).

SATURDAY, JULY 17TH.

Mr McAdam Eccles, Chairman of the Hospitals Committee, proposed and carried on behalf of the Council:—

That in all cases of accident where medical attendance is given at a voluntary hospital, and such medical attendance is covered either directly or indirectly by insurance, the hospital authorities should recover from the insurance company the full cost of maintenance and treatment of incision through the wall of the renal pelvis (pyelolithotomy) in order to avoid destruction of the renal tissue For this operation the stone must lie in the renal pelvis, it should be of moderate size and without branches, and it must be possible to manipulate the kidney so that the posterior wall of the pelvis is exposed

If the stone lies in a calyx, its position should be carefully demonstrated by means of the X rays and felt by means of a probe passed through the convex border of the kidney, so that a small incision can be made directly upon it through the renal cortex Branched stones are removed through the renal cortex by an adequate incision, and the cavity in which they lie thoroughly cleared out by irrigation and swabbing Where there is a large branched calculus and the kidney is infected, and the second kidney is normal, nephrectomy will be the best treatment

Operations for Stones in the Bladder

Small stones in the bladder can be removed by the evacuating cannula and bulb used in litholapaxy

Litholapaxy—The operation of choice for stones in the bladder is crushing (litholapaxy) In skilled hands the operation is rapid, and the convalescence short, and there is less danger than in a cutting operation Litholapaxy is contra-indicated where there is severe cystitis, enlarged prostate, diverticulum of the bladder, or growth of the bladder If the stone is a very large one, it is better removed by suprapubic cystotomy, and if there is severe sepsis of the kidneys bladder drainage by cystotomy is an important method of treatment of the kidney condition, so that this method will be chosen for the removal of the stone If the surgeon has few opportunities of treating stone in the bladder, he will probably choose suprapubic lithotomy as the operation best suited to his attainments When the prostate is enlarged or a growth or a diverticulum is present, the main surgical procedure consists in the removal of these conditions and the extraction of the stone is an incident in the operation

Provision against Recurrence

Having removed a stone from any part of the urinary tract, the question of providing against recurrence must arise In such cases careful dieting should be carried out This will usually be concerned with the reduction of oxaluria or of uric acid crystals in the urine In any case foods which irritate the urinary tract, such as alcohol, pickles, asparagus, strawberries and acid fruits, curries, peppery foods and strong coffee should be cut out from the dietary Several courses of diuretic waters such as I have described above, and a visit to a diuretic spa once a year for a few years should be prescribed

JOHN THOMSON-WALKER, M B Edin , F R C S.,
Senior Urologist, King's College Hospital ,
Surgeon, St Peter's Hospital for Stone

DONATIONS AND BEQUESTS —Mr Arthur John Pownall Brocklehurst, of Minehead, Somerset, and late of Macclesfield, left £5000 to the Macclesfield Infirmary and £1000 to the Minehead and West Somerset Hospital —Miss Mary Ethel Sim Scharlieb, B A , Harley-street, W , left, on the death of her mother, £4000 to the University of London for founding a scholarship in memory of her mother, to be called the " Mary Scharlieb Research Scholarship "—Mr John William Larkin, Crown House, Brentwood, Essex, besides other bequests, gave £1000 each to the London Hospital and the British Home and Hospital for Incurables, Streatham, £500 to the Brentwood District Cottage Hospital, and £200 to the Brentwood Nursing Association —Sir Squire Bancroft, besides many other bequests, gave £1000 to the Middlesex Hospital for a Squire Bancroft bed, and £1000 to the Chelsea Hospital for Women, for a Lady Bancroft bed —The Royal National Orthopædic Hospital, Great Portland-street, W , has received £500 from the estate of the late Mrs R I Scorer by direction of the King by his Sign Manual —The Manchester Royal Infirmary has received a legacy of £1000 from the executors of the late Mrs Elizabeth Kirkham —Various medical and other charities in the Rochdale and Oldham district as a result of the annual sports of the Rochdale County Police will receive amongst them £1200, making a total of £5000 during the last four years

BRITISH MEDICAL ASSOCIATION

ANNUAL MEETING AT NOTTINGHAM

THE ninety-fourth annual meeting of the British Medical Association opened at Nottingham on July 16th, when the Representative Body met at 10 A M in the Mechanics' Hall, with Dr H B Brackenbury in the chair

Municipal Welcome

At 11 A M the Mayor of Nottingham, Alderman Charles Foulds, accompanied by the President-Elect, Mr R G Hogarth, senior surgeon to the Nottingham General Hospital, visited the meeting to welcome the Association He remarked that its last visit had been in 1892, the year in which he had come to live in the town He referred to the changes which had taken place during the intervening 24 years and to the amenities of Nottingham as a health resort In particular was the city proud of its open spaces, which occupied nearly one-seventh of its total area Dr Brackenbury acknowledged the welcome and expressed the pleasure of the Association at revisiting the city

REPRESENTATIVE MEETING

FRIDAY, JULY 16TH

After the usual formal business, Major-General Sir Alfred Blenkinsop and Group-Captain N J Roche were elected to the Council for the period 1926–29 as representatives respectively of the A M S and R A F M S A message of condolence was sent to Dr Milner Moore, one of the " fathers " of the Representative Body, who was prevented by ill-health from attending the meeting It was agreed that the annual meeting in 1928 should be held in Cardiff, and that Sir Robert Philip, M D , F R C P E , should be President of the Association for the year 1927–28 Dr J F Hall-Edwards, a martyr to radiological research, was elected an Honorary Member of the Association in recognition of his services to medicine

In moving the adoption of the annual report of Council, Sir Robert Bolam referred to the gift of £1000 by Mrs Bishop Harman to establish a prize for research into the troubles incident to child-bearing He showed a gold and enamel badge of office presented anonymously for the use of the Chairman of Council and announced that the Council had also received a silver inkstand from Dr A E Wynter, son of the Editor of the *British Medical Journal* from 1855-61 a silver jug from the South Australasian branch, and a bust of Hippocrates from Messrs H K Lewis The Council had decided to present the gold medal of the Association to Sir Humphry Rolleston in recognition of his scientific work and his services to the profession and the Association

Sections at the Scientific Meeting

The Representative Body then considered three proposals to enlarge the scope of the scientific meeting Brighton proposed the institution of a section of the history of medicine and were supported by Edinburgh, which was particularly anxious that it should be inaugurated on the occasion of the Association's visit to Edinburgh next year, which will coincide with the Lister centenary celebrations Edinburgh also proposed sections of venereal diseases and radiology Sir Robert Bolam and Dr Brackenbury both pointed out that the Representative Body had never hitherto interfered with the arrangements for the scientific meeting It was the custom for the Arrangements Committee, composed of six local members and six nominated by the Council, to advise from year to year what sections should be held

It was agreed that the Council be requested to consider the desirability of instituting a Section of the History of Medicine at the annual meeting, and of analysis there was so far no common ground of agreement; it was the topic which most acutely divided professional opinion to-day and a pretty committee they would get Dr Parry hoped for a definite pronouncement, he congratulated him on his sanguine temperament Psycho-analysis had as yet no fixed foundation; it was at the growing point of medical theory and was totally inappropriate for committee methods It was much more properly dealt with by debate and report such as the Royal Medico-Psychological Association had instituted, so as to try and sift the truth from the falsehood The mere definition of the term would lead to a prolonged wrangle Dr Parry had said there was a public demand, but not whether the profession as a whole was longing for direction and advice He was out to condemn in advance and not to search for knowledge What was the committee to do when it had formed the opinion Dr Parry hoped for? Was it to excommunicate those who did not agree? In the long run that which was false would drop out and that which was true would stand; it would be no credit to set up a committee which might throw doubt on the truth The safeguard of the public in such matters, where enthusiasm was likely to carry people away, was to go to their ordinary medical adviser and their interests would be well looked after.

Dr R G. Gordon (Bath) said that a committee was already in existence under the auspices of the National Council for Mental Hygiene, and these were the proper people to represent all those interested in the mental welfare of the community, including, as they did some of the best legal and social services in the country. Undoubtedly there had been some abuses, but these were chiefly due to the practice of psycho-analysis by laymen, which everyone would agree was extremely dangerous, but not within the control of the B M A In a few years the abuses would fall into the limbo they deserved, partly as a result of the condemnation of the medical profession, but still more through that of the lay public Dr W Muir Smith (Eastbourne) said that the Sussex branch had not receded an atom from their original position and their object was to condemn the unnecessary emphasis of psycho-analysis on the sexual aspect of the question Dr C O Hawthorne reminded the meeting that Dr Parry was a man with a past in this matter: last year his point had been that criminal practices were so common that it was the duty of the B.M.A to express condemnation That had been refused, and now by an ingenious manœuvre he had transferred the matter to the department of the Science Committee from that of Medical Ethics Dr. Muir Smith had said plainly that those charges were not withdrawn. and clearly no reputable practitioner of psycho-analysis would sit on a committee so long as that slur on psycho-analysis remained Dr W Douglas said he saw no reason why the public should not be told what psycho-analysis was and what it did Dr H D. Woodroffe (Norfolk) spoke on behalf of the general practitioner, who was more affected than anyone else Dr. Langdon Down had said the public should go to the practitioner for guidance, and it was up to the Council to investigate for the practitioner the questions on which he had to give this guidance Dr Fothergill said that the work of psycho-analysts emphasised only one aspect of medicine, and was doing harm.

Dr R C Buist (Dundee) reminded the meeting that the B M A was a scientific association and had to realise the ways in which it could work scientifically. and asked whether the appointment of such a committee was a way of working scientifically In science one was not out for an opinion but for knowledge and knowledge in this subject did not at present exist What Dr Fothergill desired was not an open-minded committee but one in which he could destroy psycho-analysis.

Sir Robert Bolam said that there seemed to be some feeling that the Council was likely to obstruct investigations desired by the Representative Body; past history gave no colour to this The Council was willing to attempt any task laid upon it by the Representative Body, and if it found itself unable to carry out their instructions it would come back and be discharged Dr Buist had put a very important point The committee required by Dr. Parry did not ask at all the present value of psycho-analysis, which was what the general practitioner wanted to know but committed its members to an investigation of which he, the speaker, could not see the end Was the scope of the committee within practical grasp, and had the time come when it was possible to expect any result from its labours?—Dr Parry, in reply, said that this year's motion must not be judged by last year's, and that he was not satisfied to wait until he was an old gentleman; he wanted the matter settled now

The motion was carried by a majority of 56.

The General Medical Council.

Dr J S Manson proposed, on behalf of St. Helens and Warrington:

> That the Representative Body notes with satisfaction that the Council has given consideration to the recent Press agitation against the General Medical Council, but regrets that the Council, representing as it does the bulk of the profession, did not see its way clear to make a statement on behalf of the profession; further, that in the event of a renewal of the agitation, this meeting instructs the Council to issue a statement concerning the relationship of the profession to the public and asserting its confidence in the General Medical Council.

Dr Manson said that he wished this motion had come from one of the more important divisions He stigmatised the behaviour of the Council during the recent newspaper attack on the General Medical Council as 'oriental passivity' in a serious matter affecting the prestige of the profession, and compared it with the Council's activity when the capitation fee was threatened It might at least have shown approbation of the labours of others—for instance. Dr. Graham Little's skilful controversy in the Press A statement would not be enough to neutralise the campaign which had been carried on, and should be an initial step only in a defensive campaign of the B M A. in favour of rational medicine Nobody resented fair criticism, but that of the Press was not fair, but simply a brazen attempt to make the G M C accept unqualified practice.

Dr. R Langdon Down said that there was misapprehension as to the relation between the G M C., the profession. and the B M.A., and already enough confusion between the two bodies It would only be adding to this if the B M A. took the G M C. under its wing and tried to defend it against the world. The G M C was quite capable of its own defence It was most important that the B M A. should not take sides; the G M C was a judicial body and the B M A. ought not to identify itself with the judge in its courts It was easy to introduce an amplifier into such an agitation as that in the Press recently and to prolong the noise unnecessarily. the Council had been well advised to let the thing blow itself out

Dr J L Livingston said that to satisfy the people who felt something ought to be done the public misapprehension might be removed. He moved that the resolution be amended to read as follows.

> *That* the Representative Body notes with satisfaction that the Council has given consideration to the recent Press agitation against the General Medical Council and, in the event of a renewal of the agitation, this meeting instructs the Council to issue a statement concerning the relationship of the profession to the public.

This was seconded by Dr H. C Duffy. of Bolton

Sir Robert Bolam said that the amendment was very different from the motion The Press was not omniscient and he thought they had now found that much of their information had come from sources that could only be described as tainted The Council had not felt that until the eyes of the Press were opened. they could enter the arena nor was it their duty at any time to champion the G M C such patient That where patients who would ordinarily be considered as private patients are admitted to hospital solely on account of accident or emergency, they should be considered as "private patients"

A discussion followed on the motion

That case sheets and records of patients treated in hospitals should remain in the custody of the hospital, that they must be regarded as confidential documents and access to them allowed solely to the members of the visiting staff of the hospital

Dr H C. Bristowe, on behalf of Bristol, proposed an amendment by the addition to the motion of the words

and such other members of the medical profession as have the express permission of the visiting staff

Harrogate proposed to amend it by adding the words

and through the medical staff to the ordinary medical attendant of the patient, if that medical attendant so desires and the patient gives consent

Both amendments were lost after some discussion Mr McAdam Eccles and Sir Robert Bolam deprecated any weakening amendment Mr H S Souttar and others pointed out the difficult position of a visiting physician or surgeon who felt that he might at some time be compelled to show up his notes; he would probably keep two sets, one for inspection and one for his real opinions of the case The original proposition was carried

Consulting Staffs of Poor-law Hospitals

Mr McAdam Eccles proposed

(i) That the minimum fee per visit of a consultant called in to a Poor-law patient in a Poor-law hospital should be £2 2s, with mileage in addition where necessary, and (ii) that the minimum fee for each operation performed in such circumstances should be £5 5s

An amendment by St Pancras, recommending the addition of the words "the fee for a major operation being not less than £10 10s" was carried, and the substantive motion, with this addition, was passed by the requisite two-thirds majority to make it the policy of the Association

Passing to the question of regular contracts between consultants and Poor-law authorities, as opposed to sporadic attendances, Cardiff proposed

That the Council be instructed to consider the appropriate conditions of annual contracts for visiting consulting staffs of Poor-law hospitals

Dr E E Brierley, in bringing forward this motion, said that many annual contracts were being instituted, and that at present the hospitals policy of the Association gave no guidance as to the terms on which these should be arranged At the rates suggested in the motion just passed, the income of a surgeon who regularly attended a Poor-law infirmary would be quite likely to reach £2000 a year from that work alone Dr L G Glover, in withdrawing a similar motion by Hampstead in favour of the Cardiff one, remarked that in his division a local surgeon who was frequently called into the infirmary for operations had felt that his usual fees were more than the ratepayers ought to be called on to pay, and that Hampstead therefore desired the establishment of some definite scale

Dr E R. Fothergill proposed, and Dr E W G Masterman seconded, an amendment

That where the remuneration of a consultant for regular periodic visits for either of these services is on a salary basis it should be a matter of arrangement between representatives of the local medical profession and the local authority, but should have regard to the minimum fees mentioned above

Dr F Radcliffe said that divisions would be placed in a position of difficulty in making arrangements with local authorities unless they could have definite guidance as to what fee they should ask Dr J D Ewart said that the motion passed gave guidance and the conditions varied so enormously that there must be absolute freedom Dr R St Leger Brockman (Sheffield) remarked that in some places an appointment to the infirmary brought in private work as did a hospital staff appointment He supported the amendment The amendment was referred to the Council for consideration

Medical Attendants in Cottage Hospitals

Dr F. A Roper proposed on behalf of Exeter that the paragraph of the hospitals policy which states that "As far as possible every patient in a cottage hospital should have the right to be attended by his usual medical attendant" should be amended by the addition of the words

He should be responsible to his medical attendant for fees in the same way as he would be outside the hospital Where the patient has ordinarily paid mileage, such charge should be excluded, a suitable fee for each attendance being that which he would pay for attendance at the doctor's residence

He said that in the big hospitals the staff were mainly dealing with other people's patients, they reaped their reward in experience and prestige The cottage hospital was quite different, it was a small place to the staff of which every local practitioner belonged, and these practitioners could expect no gain from the appointment They sent their patients in for them to get nursing facilities unobtainable in their own homes, and not for specialist advice

After some discussion, Dr Roper withdrew the second sentence and his motion was carried as follows

That the following be added to paragraph 41 (Section XVI) of the Voluntary Hospitals Policy He should be responsible to his medical attendant for fees in the same way as he would be outside the hospital

Psycho-Analysis

Dr L A Parry proposed, on behalf of the Sussex branch.

That the Council be instructed to investigate the subject of psycho-analysis and report on the same

He said that the motion on similar lines which was referred to Council at Bath last year dealt with certain improper practices alleged to be carried on in the name of psycho-analysis This year's motion had nothing to do with that, it dealt with psycho-analysis as a whole The Central Ethical Committee had given the other motion a long, patient, and considerate hearing, but had decided not to do anything On Dec 31st of last year the *Times* had a leading article on the subject of psycho-analysis, one of the contentions being that it was time for the British Medical Association to inquire into this question and to relieve the anxiety felt by members both of the profession and of the public The correspondence which followed was almost unanimous to the same effect Sussex had again approached the Council, who had asked them to bring the matter before the Representative Body A reason brought against forming a committee of inquiry was the danger of interference with liberty of action, and of setting up a standard of orthodoxy What Sussex wanted was nothing of the kind, they only asked for a committee of sufficient standing to inquire into the whole subject The Committee on Rheumatic Diseases of Children had not been accused of setting up a standard of orthodoxy or interfering with liberty of action, and they wished psycho-analysis investigated in just the same able way Not only was there a professional demand for such an inquiry, there was also a public demand It was time that there was a committee to decide how much harm and how much good there was in the method

Dr R Langdon Down said he was glad Dr Parry did not propose to deal with the suggestions of improper practices He urged the meeting to try to picture what the proposal really meant in practice and to ask whether psycho-analysis were a suitable subject for treatment by a committee The Committee of Rheumatic Affections in Children illustrated in a practical and concrete way the difference between the two things, in that the members were dealing with knowledge and experience on which the profession had common grounds of agreement In psycho-

THE
SCIENTIFIC AND INDUSTRIAL PROBLEMS PRESENTED BY THE HORMONES.

A joint meeting of the Biochemical Society with the London Section of the Society of Chemical Industry was held on July 20th, Sir Alfred Mond, M.P., occupying the chair.

The Chairman, in his introductory remarks, referred to the hormones as the natural drugs of the body and said that the part played by these agents in the body had certain analogies with that played by the vitamins in the assimilation of food. He referred to the prominence of British workers in the scientific investigation of the hormones and in the manufacture and control of insulin, and quoted a statement made by a German scientist to the effect that British insulin was the most reliable product on the market. He emphasised the interconnexion between all forms of science and said that the fact that a division into sub-branches was a necessity should not blind us to the fact that science was an indivisible whole. Success could only be achieved by coöperation between industrial and laboratory workers. In the absence of this cooperation one or other must eventually suffer. There was, he thought, a modern tendency to ignore the fact that fundamental advances were always made by the thinker and inventor rather than through commercial enterprise.

Dr. H. H. Dale read a paper on the

Experimental Study and Use of the Hormones.

He began by a general review of the recent developments in the science and practice of the treatment of disease. Amongst the most important of these was the discovery of the hormones and their use, both in the treatment of disease and in the maintenance of normal health and development.

Suprarenal Gland.—Dr. Dale gave a brief account of the discovery of the active principle of the suprarenal gland and of its mode of action. This, he said, closely resembled the effects on the different organs of the skin and viscera produced by the nerves of the true sympathetic system. In every direction the visceral reactions were such as to prepare the organism for combat or flight. In addition to this emergency function, the constant presence of traces of this hormone in the blood was necessary for the maintenance of healthy tone in the peripheral blood vessels and therewith of an adequate supply of well-regulated nourishment to the tissues. In therapeutics apart from its action in relaxing the bronchioles in spasmodic asthma adrenalin was mainly used in surgery for its local vaso-constricting action. Adrenalin was the first of the hormones to be separated in a state of purity. It proved to be a relatively simple aromatic amine, difficult to work with only on account of its ready oxidation. Its synthesis soon followed. The problem of its origin in the body, however, still remained to be solved.

Dr. Dale then referred to the functions of the suprarenal cortex of which he said little was known beyond the fact that its activity was in some way connected with the development of sexual maturity.

The *thyroid gland* furnished the earliest and most successful example of treatment by administration of a missing hormone. Long before the identification of the active principle it was recognised that absence of the gland or defect of its secretion led to retardation of oxidative metabolism, with resulting myxœdema or cretinism. The activity of the gland was also known to be roughly proportional to its iodine content, but it was not until about ten years ago that the active iodine containing hormone was first isolated in pure crystalline form by Kendall in America, and named by him "thyroxine." Recent investigations by Dr. Harington had shown the way to its preparation in practicable quantities.

Dr. Dale briefly described the properties of thyroxine, which, he said, was an intensely active substance, with an action which, in contrast to adrenalin was slow in developing, but persisted for some time. The intravenous injection of 10 mg. of thyroxine would raise the metabolism of an individual 45 per cent. above the normal rate by the fifth day. The effect did not subside completely for a fortnight.

Pituitrin, insulin, and secretin were either protein derivatives or closely associated with them; they were therefore sensitive to the action of proteolytic enzymes and were rapidly destroyed by autolytic enzymes appearing in the glands containing them immediately after the death of the animal. For the same reason, unlike thyroxine, they had little action when given by the mouth.

The *pituitary gland* consisted of two portions, the anterior and posterior, with different morphological origins and functions. The active constituents of the anterior lobe had not yet been separated. The posterior lobe yielded an extract with a powerful vaso-constrictor action; it also acted on the muscle of the uterus and hence was invaluable in obstetrics. The commercial preparation of the drug was relatively simple, provided the material was fresh, as an extract of high potency could be obtained by simple extraction with boiling acidified water. The separation of the active principles of the posterior pituitary, in order to study their chemical nature, presented many problems of extraordinary difficulty, largely owing to the enormous quantity of the raw material which was required to obtain an adequate quantity for such work.

Pancreas and Insulin.—Dr. Dale went on to discuss the possible causes for the failure of all the earlier attempts to separate the active principle of the pancreas. He attributed this failure partly to the difficulty in removing the insulin from the destructive influence of the pancreatic trypsin, and partly to the probable presence in the pancreas of other principles having an antagonistic action and therefore needing elimination. Another factor was probably the ease with which the insulin falls out of solution at a reaction of pH 5. Insulin could now, he said, be obtained in a state of relative purity and intense activity. Prof. Abel, of Baltimore, claimed to have isolated insulin as a pure crystalline substance, but it was as yet too early for final judgment of this claim. The separation of insulin had already thrown a flood of new light on the intermediary metabolism of the carbohydrates, and on the inter relation between insulin on the one hand, and adrenalin, pituitrin, and thyroxine on the other.

Biological Standardisation.—Dr. Dale then referred to the necessity for accurate dosage, and mentioned the disastrous results of a lack of uniformity in biological standardisation, emphasising the necessity for adoption of internationally valid units both for pituitrin and insulin.

Dr. Dale in conclusion said that coöperation was not only essential between the manufacturer and the laboratory worker, but also between the workers themselves, and he asked whether competition was really inseparable from industry in matters of this kind. As an instance he quoted the manufacture of parathyroid. There was, he said, not more than enough material in the country to keep one small manufacturing laboratory going; it therefore did not seem worth while to split up the limited amount of raw material at our disposal, as this was uneconomical and merely meant that in the long run we should have to procure our supplies from abroad.

Dr. H. W. Dudley read a paper on the

Chemistry of the Pituitary Gland and of Insulin.

He dealt first with the practical difficulties encountered in the attempts to isolate these principles. In the first place there was the cost of the raw material which was almost prohibitive to the acquisition of adequate quantities. He calculated that in order to

Dr J W Bone objected to instructing the Council to issue statements under hypothetical circumstances

Dr Livingston's amendment was carried as an amendment, but when put as a substantive motion was lost

Appeal from the Decision of the G M C

Dr C L Morgan proposed, on behalf of Hastings.

> That in the opinion of the Representative Body, if and when the status, constitution and disciplinary powers of the General Medical Council come under consideration for amendment, the Council should take all possible steps to have provided the opportunity for an appeal being made to the courts from any disciplinary decision of the General Medical Council

He said that if the powers of the G M C were to be reviewed it was the time for the Council to consider the matter of appeals Hastings thought that miscarriages of justice might occur and that there should be some appeal

Dr C G H Morse proposed an amendment by Bournemouth

> That the Council of the Association be instructed to take the necessary steps for securing such amendment of the Medical Acts as shall provide for a right of appeal from the decisions of the General Medical Council (say, for example, the Judicial Committee of the Privy Council, sitting with Medical Assessors) when such body acts in a judicial capacity in cases of alleged "conduct infamous in a professional respect"

He drew attention to the fact that two separate divisions had come independently to the decision that there should be some appeal; it was merely the right of any British citizen His division had little doubt that the right decision was nearly always arrived at, but those who read the reports would feel that miscarriages did occur There had been sufficient evidence in the last half year that the G M C did not hold the confidence of the public nor of the profession as it ought to If there were a court of appeal which upheld the decisions of the G M C its prestige would be enormously increased Since the G M C was established, with that blunderbuss accusation of "infamous conduct," things had profoundly changed With the National Health Insurance Act and the Dangerous Drugs Act practitioners had come much more into the public eye and under public control, and into increased danger of accusations He did not think that the right to appeal would be abused, the man who would appeal would be the decent fellow who had made some little slip and who felt justice had not been done, the rotter, who did not wish to conform, would not lodge an appeal There was no reason why the G M C should be wholly medical, although it was preponderantly so The appeal suggested was on points of law, but could not be to the ordinary courts, there must be one or two medical assessors sitting with the judge

The Chairman suggested that members of the General Medical Council who were present should tell the meeting exactly what happened when penal cases came before that body and the deliberations were conducted in camera for a time

Later, Sir Jenner Verrall said that it was curious that the phrase "infamous conduct in a professional respect," which had aroused so much criticism, had been perpetuated in the most recent development of professional judicature—the Medical Act of Queensland He did not think it right for him to express any opinion on the motion, but hoped that, if any court of appeal was pressed for, it would include medical men No profession was so difficult to understand as the medical, and he suggested strongly that the General Medical Council was quite as capable as an ordinary jury of deciding medical questions Ordinary appeal law laid it down that the appeal should be decided by one judge, he thought it would be most unwise, unfortunate, and dangerous to submit medical matters to such an eventuality

Dr J A Macdonald said that after 15 years of experience of the General Medical Council and of the extraordinary care with which cases were considered, he felt sure that the profession could not be in better hands

Sir Robert Bolam said that he had gone to the G M C with a superficially-formed idea that he would enter as a young and ardent spirit to a collection of old fogies, he had found nothing of the sort In the chair was one of the acutest minds in the profession, a successor of equally eminent minds, surrounded by men of widely differing temperaments, grades of opinion and experience; by no means mere academicians He did not know what the complaint was, if it was that the G M C were too severe he would remind them that it consisted of men who had trained generations of medical students and had experience of their difficulties Most of the members were nominated by the bodies which examined and licensed the profession Why was a change desired? He urged the meeting to think very seriously before plunging into the maelstrom of Parliamentary procedure

Mr W E Hempson, the solicitor, in reply to a number of questions, said that the procedure of the Council was peculiar to itself; evidence was in the form of statutory declarations The deposers had to swear, or declare solemnly and sincerely, that the matter in these declarations had been proved The respondent had the advantage in that he was not compelled to answer the charges on oath, or indeed in any form at all The speaker objected to the terms "prosecution," "defendant," &c, which were so often used The words should be "inquiry," "complainant," "respondent" The Penal Cases Committee sifted the evidence before the cases were heard, and acted as a kind of Grand Jury

The Chairman, in reply to a question, said that of course if appeal were allowed it would cut both ways and the complainant could also appeal

Dr Radcliffe asked whether it would be possible for an appeal court to impose a monetary or other penalty beyond the only penalty of the G M C—removal from the Register

Sir Jenner Verrall replied that appeal would probably only be a question of rehearing, but it would of course depend on the nature of the tribunal set up

It was finally agreed to pass to the next business

Dr J W Bone, opposing a motion by Willesden,

> That the Representative Body is of opinion that the time has arrived when the Medical Acts should be amended so as to provide for a larger direct representation of registered medical practitioners on the General Medical Council, and that it be an instruction to the Council to take all possible steps with a view to bringing this into effect,

said that the Medico-Political Committee had gone into the matter fully and had decided that any attempt to alter the constitution would arouse the opposition of the Privy Council, Parliament, and the public The General Medical Council was always being stigmatised as too powerful, and any disturbance of its present form would arouse an agitation which would result in the whole thing going into the melting-pot, with a risk of the profession losing the privilege of disciplining its own members

The motion was rejected

Minimum Salaries for Public Health Medical Officers

In moving the recommendation of Council

> That the Representative Body strongly urges all divisions and branches in England and Wales which have not already adopted a resolution under their ethical rules in relation to the scale of minimum commencing salaries for public health medical officers to take steps forthwith for the adoption of such a resolution,

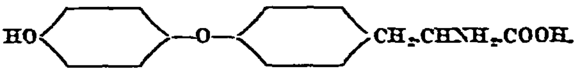
Dr R Langdon Down said that it was much better for a division to adopt a principle before a concrete case arose, as it was then in a much stronger position in expressing disapproval

The recommendation and the remainder of the annual report under "Medical Ethics" was approved

During the day it was announced that Dr H B Brackenbury and Dr C O Hawthorne had been returned unopposed as Chairman and Deputy-Chairman respectively of the Representative Body

(To be continued)

$C_{15}H_{11}O_4NI_4$. He established the constitution of desiodothyroxin by degradation and by synthesis as



Of this substance thyroxine is a tetra-iodo substitution derivative; the position of the four iodine atoms has not been ascertained.

Prof Barger showed lantern slides to illustrate the effects of the administration of small quantities of thyroxine to cases of myxœdema and to cretins He also showed photographs of a completely thyroidectomised cat, surrounded by white mice, to illustrate the complete apathy induced by this condition.

Dr J. W. Trevan's paper on the Biological Assay of Hormones was not reached on the programme.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Cryptotoxins

VINCENT has been engaged in studying the neutralisation of tetanic and other toxins by sodium salts of the fatty acids, such as oleic, margaric and palmitic acid He finds that these salts especially sodium palmitate combine with the toxin and render it harmless. He has worked with the toxins of tetanus, diphtheria, typhoid, dysentery, and other affections. The quantity of sodium palmitate required for neutralisation is minute, 1/100 mg neutralising 100 lethal doses. Sodium palmitate forms a very stable combination with the toxins, which are not merely adsorbed The toxins are not destroyed by combination, but may be released by careful titration with an acid (HCl) The term cryptotoxin has been coined for these new substances. They produce a certain degree of immunity when repeatedly injected. The palmitate of sodium is said to be not only antitoxic in the way described but bactericidal for bacilli of cholera typhoid diphtheria, dysentery and for many other bacteria.

Death of Teissier.

The Faculte de Medecine sustains a severe loss in the death of Joseph Teissier, well known for his work in pathology, general medicine, and infectious diseases He was chief at the Claude Bernard Hospital at Paris which is devoted to the isolation and study of contagious diseases. Exacting and thorough as a teacher, Teissier impressed all who came in contact with him as a profound and perfectly independent student. He was a clinician par excellence. His students will remember his bedside demonstrations with appreciation and he leaves at the Faculte, a place which will be difficult to fill

An Anæsthetic Mixture

Desgouttes and Ricard, of Lyons, find that a mixture of ten parts ether, seven parts chloroform and three parts ethyl chloride is admirable for general anæsthesia when given with a closed apparatus, such as the Ombredanne mask. It must be given in large quantities if administered by the open method. With the Ombredanne mask, 30 g of the mixture suffices for 35 to 40 minutes The index on the mask should be gradually moved up, to reach 5 or 6 in about ten minutes. It should rarely be moved higher than 6 The anæsthesia so produced is tranquil and undisturbed, the post-anæsthetic stage passes off with but little vomiting and pulmonary complications are minimal

Immigration and Disease.

The General Council of the Seine has referred a Bill to its Third Committee proposing health examinations of all persons filing naturalisation papers in France. This proposal does not go very far towards relieving the French hospitals of their burdens, for relatively few of the foreigners cared for are naturalised or have any idea of seeking French citizenship. The problem is a vexed one, for large cities in any country must care for the sick poor of whatever nationality. The establishment of a strict sanitary frontier would be far more effective than the insufficient provision mentioned above.

Resolutions against Alcoholism.

Prof M. Labbé has presented to the Academie de Médecine the results of exhaustive studies made by him on the abuse of alcoholic beverages in France. The Academie after considering Labbe's report, has forwarded resolutions to the French Government, which demand stricter regulation of alcoholic beverages control of absinthe and its substitutes reduction of the privileges now granted to wine and liquor producers encouragement of the use of non-fermented grape and fruit juices, and a campaign of popular education

The Paris Municipal Council has just reported favourably upon a resolution to provide financial aid for hospital interns affected with tuberculosis French interns are employed by the Assistance Publique, and are therefore Government employees.

Legislation is being prepared for active suppression of small-pox in France. It refers to more frequent revaccination, and includes rigid regulations for either vaccinating or exacting proof of an effective vaccination from all foreigners entering France.

A post-graduate course in dermatology will be held at the Hôpital St. Louis, Paris under the direction of Prof. M Jeanselme, from Oct. 4th–30th, and a course in venereal disease from Nov 3rd to 27th Particulars may be had from Dr. Burnier at the hospital

A new Cancer Institute at Paris is to be erected on a site at Villejuif one of the suburbs of Paris and will be directed by Prof. Roussy.

On July 4th a meeting in honour of the memory of Thomas Jonnesco was held at the Faculte de Medecine. Jonnesco was formerly prosector at the University of Paris, and Levaditi was one of his pupils.

The Services.

ROYAL ARMY MEDICAL CORPS

THE undermentioned Cols., late R.A.M.C to be Maj-Gens.: H P. W Barrow, and to be supernumerary: D Harvey, and to be supernumerary: and J S Gallie vice Maj-Gen. J. R McMunn, to ret. pay.

Lt.-Col. E P. Sewell, from R.A.M C., to be Col., to complete estabt

Lt.-Col. A. E. Hamerton to be Bt. Col.

The undermentioned Majs to be Lt-Cols.: N E Dunkerton vice Lt.-Col. O W. A. Elsner, to ret. pay, and Bt. Lt.-Col. P. J. Hanafin vice Lt.-Col W A. Woodside, to ret. pay.

INDIAN MEDICAL SERVICE.

Col. F H. G Hutchinson to be Maj-Gen.

Capts W. P. Hogg, Vaman Raghunath Mirajkar and Mohamed Mossa Khan to be Majs.

The King has approved the grading as Captain of G. H. Fitzgerald.

Wajid Ali Khan to be Temp Lt.

WEST AFRICAN MEDICAL STAFF.

Dr M B. Hay has been appointed to be a Senior Sanitary Officer in the West African Medical Staff, for service in the Gold Coast as an addition to the establishment.

prepare 100 gr. of the pure active principle of the posterior lobe of the pituitary, it would be necessary to work up material from 1,000,000 oxen. In the case of insulin the same situation prevailed, although the raw material was more easily available. On turning to the chemical investigation of these substances, difficulties arose owing to their extreme complexity and instability.

Pituitary Hormones.—By treating the posterior lobe of the pituitary with faintly acidulated boiling water a filtrate could be obtained which contained substances which made plain muscle contract, and which caused a rise in blood pressure. The question as to whether these effects were produced by one hormone or by two was as yet undecided, but Dr. Dudley inclined to the view that there were two active substances with a very similar chemical constitution. The plain muscle-stimulating substance had the following properties: it was destroyed by boiling with strong mineral acids and rapidly inactivated by dilute alkali; this led to the view that it might be an ester. It was not destroyed by pepsin, but was destroyed by trypsin, which led to the belief that it might contain the peptide linkage characteristic of proteins; this view was strengthened by the fact that it was not inactivated by the ester splitting enzyme lipase. The literature contained records of crystalline salts having been prepared, but these observations had not been substantiated. Probably an apparently pure crystalline substance could adsorb a sufficient quantity of hormone to render it physiologically active.

Insulin.—This substance was prepared by extraction with aqueous alcohol which precipitated most of the protein, higher concentrations of alcohol finally precipitating the crude insulin. This could be further purified by various methods, a convenient one being the precipitation of insulin as an insoluble picrate, which can then be converted into a soluble hydrochloride. Such preparations, though very potent, were by no means chemically pure. They gave many of the usual protein reactions and contained from 12 to 15 per cent. of total nitrogen. They also contained organically bound sulphur, but so far this sulphur content had not been correlated with the physiological activity. Recently Prof. Abel had suggested that a portion of the total sulphur was actually an index of the physiologically active hormone present. He had also announced the preparation of a crystalline substance which he considered to be pure insulin. Dr. Dudley concluded that the properties of insulin were all in keeping with the view that it was a protein-like substance, or, at any rate, a substance associated with a protein fraction in such a way that hydrolysis of the protein inactivated the insulin.

Mr. F. H. CARR read a paper on the

Commercial Production of Hormones.

He first discussed the preparation of insulin in all its stages. The collection of the raw material was a most important point. The pancreas, immediately after excision from the animal, was trimmed to remove all other tissue, and it was then quickly frozen. This was done by placing the glands in thin layers in a room of which the temperature was −5°, or colder. Rapid freezing was procured by circulation of cold air. He described the means by which this was done, the air being dried at the same time by means of calcium chloride. The raw material was then rendered acid in order to stabilise it; this was done by a method of grinding with continuous incorporation of acid and alcohol. As the grinding could not be done without the generation of heat, special methods had to be employed, by which the grinding was done in two stages, between the first and second of which alcohol was incorporated. The final result of this stage was a fairly stable product containing 65 per cent. of alcohol and having an acidity of pH 3.5. Filtration and clarification were then carried out. The next stage was that of concentration. Here again time was an important factor, and the method of vacuum evaporation had proved the most satisfactory. The insulin was then purified by fractional separation by precipitation with alcohol or other protein precipitant. Purified insulin was insoluble in water at pH 5, but was relatively soluble at this point when other associated proteins were present. Insulin was also precipitated by half saturation with ammonium sulphate at all reactions, but the purification of the mixture of albumoses so obtained was difficult. The ultimate purification of insulin was done by precipitation with picric acid and subsequent regeneration as the hydrochloride as suggested by Dr. Dudley. In large scale operations there was always a loss of insulin during the various stages, and determinations of pH, alcohol percentages, and blood-sugar reducing power must be made from time to time in order to insure success. Mr. Carr then described briefly the preparation of thyroxine, which was done by Harington's recently published method. This consisted in hydrolysing the gland in two stages, first with 10 per cent. and then with 40 per cent. baryta water; the gland was then further treated with aqueous caustic soda for 15 minutes. The two liquids so produced were boiled with strong baryta for 18 hours, leaving an insoluble precipitate of a barium compound of thyroxine. The same precautions should be used in collecting and storing the gland, as were indicated above for when discussing the pancreas. The advantages of thyroxine were the ease with which its purity could be determined and the accuracy of the dosage.

Dr. H. A. D. JOWETT read a paper on the

History of Adrenalin.

He said that adrenalin was up to the present the only hormone whose chemical constitution had been finally established beyond all doubt by its synthetic production. The medical and physiological importance of the suprarenal glands was realised by Addison in 1849, but it was not until 45 years later, in 1894, that Oliver and Schafer observed the rise of blood pressure resulting from intravenous injection of suprarenal extracts. As a result of this discovery suprarenal extracts then began to be used as hæmostatic agents. Successful isolation of the hormone was accomplished by Takamine in 1901, the active principle, which he named adrenalin, being precipitated by the use of a large quantity of strong ammonia. The formula was determined in 1901 by Aldrich. In 1903 Pauly confirmed this formula and found that adrenalin was optically active, and in 1904 Jowett finally established the constitutional formula. Synthetic production of the base in 1903 was accomplished by Stolz from catechol. The resulting adrenalin was optically inactive. The next step was then to resolve the synthetic racemic adrenalin into its optical isomers; this was effected by Plack in 1908. It appeared that *d*-adrenalin was not entirely inactive, but the ratio of the activity between the *d* and *l* isomers was 1–15. The synthetic process had now been worked out on the commercial scale, and synthetic adrenalin was sold under the name of suprarenin synthetic. A considerable amount of work had been done on allied problems, and methods for determination and detection of adrenalin had been worked out. Other methods of synthesis had also been tried. In conclusion, Dr. Jowett said that very little was known as to the way in which the suprarenal gland synthesised adrenalin, but that the working out of the constitution of the hormone paved the way for an attack on this problem.

Prof. G. BARGER read a paper on

Recent Progress in the Chemistry of Thyroxine.

Thyroxine, he said, is a crystalline active principle of the thyroid gland, first isolated by E. C. Kendall.[1] The method of isolation was recently enormously improved by Harington,[2] who obtained a yield more than 20 times that of Kendall. Harington further showed that the substance has not the formula $C_{11}H_{10}O_3NI_3$ attributed to it by Kendall, but

THE R S M AND BIBLIOGRAPHIES

To the Editor of THE LANCET.

SIR —I have received notice from the Royal Society of Medicine that the library staff will in future provide references and bibliographies on request from any Fellow The reason for this arrangement is doubtless that practitioners and provincials cannot find time to visit the library, but can read books forwarded to their homes To object to authors being content to accept references at second-hand is perhaps over-scrupulous, and possibly medical literature would not suffer from the arrangement provided the authors actually read the articles in the lists supplied The arrangement lends itself however only too easily to the practice of spuriously embellishing articles with references which the writers have not taken the trouble to verify and read critically themselves Many who have examined literature must have suffered from such meretricious adornment of articles, particularly in American journals; and in America the arrangement is common Surely any advantage likely to accrue to British medical literature from the arrangement cannot counterbalance the exposure to this abuse

I am Sir, yours faithfully,

London, July 14th, 1926 HUBERT M. TURNBULL.

NON-SPECIFIC PROTEIN INJECTIONS IN CHRONIC ARTHRITIS

To the Editor of THE LANCET.

SIR,—Dr M B Ray's comments in THE LANCET of July 17th upon this subject are of great interest, and his reasoned explanation of the cause of arthritis and the rationale of its relief is very instructive Our views though not identical, have much in common It is agreed that the fault lies partly in imperfect breaking down of chemical substances by the cells and the consequent presence of irritating intermediate products in the fluids of the body. The abnormal products can be destroyed by increasing the oxidative power of the cells, and in this fever plays an active part Faults of elimination through the skin are too important to be ignored, it is to delayed correction of skin lethargy that the familiar "bath reaction" of which Dr Ray speaks is due When the inertia of the skin is overcome and adequate sweating is produced this reaction disappears

I am, Sir yours faithfully,

London, W, July 17th, 1926 C E SUNDELL

HEART DISEASE AND EPILEPSY

To the Editor of THE LANCET

SIR,—To THE LANCET of July 10th Dr Moon contributed an interesting and suggestive note on this subject Obviously he is not aiming at treating it exhaustively as he makes no mention of the association between paroxysmal tachycardia and epilepsy, of which his wide clinical experience must have afforded examples—relatively rare as is this association It has been of interest to me since the year 1903, when I published notes of a case in Vol XXI of the *Transactions* of the Royal Academy of Medicine in Ireland In brief, the case was that of a girl, aged 14, with a family history of epilepsy, the subject of frequent minor and occasional major fits, and of attacks of paroxysmal tachycardia intermingled, seeming to replace the former At the time I could find no detailed record of this association, merely that paroxysmal tachycardia had been called fancifully "epilepsy of the heart" My next case was that of a gentleman aged 60 whose epilepsy had disappeared for 16 years till convalescent from an operation He was then suddenly seized by paroxysmal tachycardia lasting till I saw him some hours later, when it ceased instantly with "vagus compression" Three days afterwards he had a severe epileptic fit.

From these and other cases which I have observed, or heard of, in which this association was more or less intimate, it would seem that, in a certain group, some common factor underlies both conditions, probably a neurotic one, and that this factor may manifest itself as paroxysmal tachycardia purely. Certain it is that cases of this condition are met with in neuropathic subjects, with a probable family or personal history of fits, who do not develop demonstrable cardiac lesions other than the paroxysmal arrhythmia, and with whom one gets the surer therapeutic results by discounting the heart symptoms and treating as for epilepsy, without suggestive mention of that dread name.

In exemplification of Dr Moon's observation of how well a damaged heart can deal with the strain superimposed by epilepsy, I can recall the case of a gentleman who was under my care for ten years He reached the age of 70 (and may still be alive) despite the fact that from his early twenties he had major fits that never relented in their incidence for longer than a month, and who from boyhood had pronounced aortic regurgitation, evidently produced by some acute, but non-progressive infection.

I am, Sir, yours faithfully,

R TRAVERS SMITH, M D, F R C P. Irel.

London, W, July 16th, 1926.

NEW DANGEROUS DRUGS REGULATIONS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of June 19th attention was drawn to certain proposed new regulations concerning dangerous drugs. At a recent meeting of the Council of the National Medical Union the following resolution, which speaks for itself, was carried unanimously.—

> "That the Council of the National Medical Union, after careful consideration of the whole subject of the proposed new Dangerous Drugs Regulations, takes strong exception (1) to the proposal to set up a tribunal composed of three medical practitioners and one legal assessor to deal with cases of infringement of the regulations, instead of these cases being dealt with, as at present, by the ordinary courts, (2) to the proposal to empower the Home Secretary to withdraw from medical practitioners found guilty by the said tribunal the right to possess and even to prescribe dangerous drugs, such penalty having the effect of making it impossible for such medical practitioners to continue in practice, (3) to the proposal to make the Home Secretary the final authority without right of appeal to the courts of law, which proposal is contrary to the basic principles of British justice, (4) to the proposal to place upon non-dispensing practitioners the obligation of keeping records of their purchased supplies of the dangerous drugs, on the grounds that the properly made out prescription or order, which is retained by the wholesale or retail chemist, contains all necessary information and is sufficient safeguard"

The National Medical Union lodged a strong protest against the new regulations within the time required under the Rules Publication Act, and the Home Office has a statutory duty to consider their objections

The attempt which is being made in various directions to bring the members of our great profession under bureaucratic control must be met at once and resisted to the utmost, otherwise we shall find ourselves before very long as pawns in the hands of incompetent officials and Government inspectors. Evidently the Home Office has found that it has not always been able to secure a conviction when bringing cases before the courts With the new regulations in force no doubt this difficulty would be partly overcome There is no reason why medical practitioners who break the law should be dealt with without proper trial in a court of law. I shall be glad if medical practitioners who are interested in the matter will kindly communicate their views to me.

I am, Sir yours faithfully,

S. G ASKEY,

Hon. Sec of the National Medical Union

11, Chandos-street, Cavendish-square, W, July 19th 1926.

ROSS INSTITUTE AND HOSPITAL FOR TROPICAL DISEASES.

On July 15th the Prince of Wales opened the Institute now established at Putney as a memorial to the work of Sir Ronald Ross and as a centre for research and treatment The appeal for such a memorial was issued in 1923, but the promoters found it by no means easy to secure a suitable building The freehold of Bath House, a modern mansion standing on the edge of Putney Heath, was eventually acquired, and under the scheme of Mr G Berkeley Wills, F R I B A, three research laboratories, two wards, and a library have been installed The house has enough ground of its own to permit further extension if need be, and it overlooks pleasant country

The work of the Institute has already begun Its main purpose will be intensive research into the prevention and treatment of tropical disease, but it will also serve as a propagandist centre for handing on information to workers abroad and for stimulating control work in malaria and other tropical and subtropical diseases Unlike the schools of tropical medicine, the Ross Institute will not be a teaching centre, but medical men home from the tropics will be allowed the use of the laboratories for research

His Royal Highness was received by the Duchess of Portland (the President) and by Sir Charles McLeod (chairman of council), who presented an address of welcome recording the many benefactions received from business houses in all parts of the Empire, from Overseas Governments, and from the general public The proposal to found such an institute, he said, had met with immediate and sympathetic response from leading members of the medical profession in Great Britain, the United States, France, and Italy To continue the work of the Institute in fullest efficiency the committee was appealing for continued support to meet current expenses and also for the creation of an adequate endowment fund

The Prince of Wales, in opening the Institute, said "The opening of this Institute, which I am very glad to perform, commemorates a definite achievement in the work which the British Empire has done for civilisation Not the least important obligation which the development of that Empire has laid on the members of our race is the constant struggle against disease in all the varied forms it can assume in different climates and in different latitudes The struggle is always fiercest in the tropics, where man, and especially the white man, is the continual prey of diseases from which we in this country are, comparatively speaking, protected by a more temperate climate, and perhaps the saddest page in the whole history of our Empire is that which tells of the terrible toll taken by plague and by fever of those who helped to build it

"Of all these tropical enemies, malaria has probably been the most deadly and elusive But now, thanks to the achievement of one man, whose name we are perpetuating in this Ross Institute, its ultimate defeat is certain Only a few months ago I was able to see in the Sir Alfred Jones Laboratory in Sierra Leone not only the vital need for a campaign against malaria but also the remarkable progress which has already been made in it Perhaps I am biased by many visits to tropical and subtropical parts of the world where malaria is rife, and by having talked with so many men and women whose health has been shattered by a life's work in such districts, but I can think of no other single discovery in recent times which will earn the deep gratitude of so many thousands of human beings of all nationalities as the discovery made in India by Major Ronald Ross—as he was then—on August 20th, 1897 The story of its subsequent development and of what it has led to is well known to you all. I need only summarise it in the words of a famous writer 'It is not too much to say that Sir Ronald Ross has made one-third of the world inhabitable'

"Over a quarter of a century has elapsed since that epoch-making discovery, and this Institute and Hospital now stands as a memorial to the life-work of Sir Ronald and his colleagues But it is not merely a passive memorial to work accomplished in the past, it is also, as Sir Charles McLeod has just reminded us, a very active centre for work to be done in the future All who have any experience of the tropics will know that there is still a vast field for scientific medical research, and here, with all the sources that modern science can provide, such research can be effectively carried out, provided adequate funds are forthcoming From this building may issue results which will bring back health to thousands who have lost it, or safeguard the lives of countless others threatened by unseen dangers in tropical lands More than that, it may open out, for the use and benefit of mankind as a whole, huge districts which are at present denied to civilisation

"It is not surprising, therefore, that when the scheme for founding this Institute was first put forward it immediately received widespread public support That support happily made its inception possible, and once the first financial obstacle was surmounted its promoters lost no time in making it a reality To the President, the Duchess of Portland, to Sir Charles McLeod and Mr Shakespeare, and to Sir Ronald and his two co-directors, Sir William Simpson and Dr Castellani, the gratitude of all of us is specially due for the time and energy they have devoted to its execution They and their fellow officers of the Institute may well feel proud of the result of their labours and of the knowledge that they have called into being something which cannot fail to be of incalculable benefit to many generations

"It is with the sincere hope that further public support for the necessary endowment may be forthcoming, and that the labours of those who will work here may be blessed with every success, that I now declare the Ross Institute and Hospital open"

A vote of thanks to the Prince of Wales was proposed by the Duchess of Portland and seconded by Sir Ronald Ross, director-in-chief, who said that the Prince's words would bring vividly before everyone in the British Empire some sense of the terrible loss which malaria inflicted on the world and some idea of the need to overcome it On behalf of his associates he acknowledged the ready and generous assistance given by more than 1000 contributors headed by His Royal Highness, no fewer than 15 tropical dependencies and eight rulers of States had helped Sir Ronald Ross said that he was particularly grateful to the Prince for the kind way in which he had referred to his work, hundreds of workers in the field of tropical medicine had done their bit He himself could only expect to view from afar the promised land of a perfectly sanitated world, but, at least the Institute could be left in the best possible condition for future use as a centre for study and a home of sound research

---

Poplar Hospital for Accidents—Last week the Lord Mayor of London (Sir William Pryke), who was accompanied by the Lady Mayoress and the Sheriffs, opened a new nurses' home, which has cost £30,000, at this hospital The Lord Mayor recalled that the hospital was originally housed, 70 years ago, in the buildings of the old Custom House

Grants for Local Services—According to a statement made by Sir John Utting to the Liverpool Port Sanitary and Hospital Committee, the city will lose £110,000 a year if the Government carry out their proposal to replace the 50 per cent grants for local services by block grants Liverpool is spending £180,000 a year on tuberculosis alone —according to Sir John Utting 50 per cent more than any other municipality The change would involve either an addition of 4*d* to the rates or a curtailment of the tuberculosis work.

HELEN BEATRICE DE RAZTRICKE HANSON, M D, B S LOND, D P H OXF

ANOTHER victim was added to the long list of motor casualties in London streets when, on July 6th, close to her home, Dr Helen Hanson was struck by a passing car and killed almost instantaneously.

Helen Hanson studied medicine at the London (R F H) School of Medicine and was a keen and capable student. After qualifying M B B S Lond in 1901 she held resident posts at the Bristol Children's Hospital, the Morpeth County Asylum, and the St Pancras Infirmary. She then went to India as a medical missionary and was attached to the Kinnaird Hospital, Lucknow, where she was much beloved by patients and colleagues. She was the principal surgeon to the hospital and performed a large number of major operations. The climate affected her health and she was invalided home after three years' service. In 1911 she became assistant medical officer to the L C C, a post to which she returned after a break during the war. To school medical work she devoted great energy, never forgetting that prevention of disease was the object to be arrived at. She took a personal interest in the nurses who worked under her, and was very popular among them, and her care of the children was maternal.

When the war broke out Dr Hanson volunteered at once for foreign service. She went through the siege of Antwerp with Mrs Stobart's unit, and escaped, among the last to leave, on the top of a motor 'bus packed with ammunition. Later she went to Serbia where she was established in a hospital under canvas at Kragujevatz and found again opportunity to do much surgical work. She left Serbia during the summer of 1915, before the last invasion of the country, and returned to England through Russia. Shortly afterwards she became a temporary medical officer in the R A M C and was sent first to Malta and afterwards to Salonica, where she remained till the Armistice. Against the persistent refusal of the authorities to give commissisons to women medical officers, which meant loss of prestige and many real difficulties and disadvantages, Dr Hanson made repeated protest, based on personal experience. Her next move was to Constantinople with the Black Sea Expeditionary Force, where she remained until 1920, when she returned home via Palestine, a journey which was to her full of interest and enjoyment, and stirred her religious feelings deeply.

Dr Hanson was a woman of many and varied interests. It has been said of her that "she had a genius for friendship." Her friends were indeed legion and none was ever forgotten. In her family circle she was a most devoted daughter and sister. Her loss is one which will leave a blank in many lives.

ANDREW RAE [WILBUR] WRIGHT, D S O, M B,

BREVET LIEUT-COL., R A M C

THE death of Lieut-Colonel Wright on June 30th at the comparatively early age of 45 which occurred at the Government General Hospital, Madras from appendicitis has cut short a career of great promise, but it is some consolation to reflect that it was already a career of high achievement.

Born at Wigan in 1881, Colonel Wright was the younger and only surviving brother of Prof William Wright, dean of the London Hospital. He received his professional education at the Owens College, Manchester. After graduation he held amongst other appointments those of house physician at the Manchester Royal Infirmary and senior resident medical officer at the Infirmary Crumpsall. In 1908 he joined the R A M C in which corps the remainder of his life was spent. After the usual preliminary course at Aldershot he was posted to Malta, where he was stationed when war broke out. Attached as regimental medical officer to the 2nd Battalion of the Royal Warwicks, he disembarked at Zeebrugge on Oct 6th, 1914, and took part in the memorable rear-guard action fought by the 7th division around Bruges, Hansbeke, Ghent, Thielt Roulers, and Menin. On Dec 31st he was posted to command C Section of the 21st Field Ambulance, and on April 19th, 1915, to be second in command of No 10 Casualty Clearing Station at Hazebrouck. When it was decided to introduce the practice of pitching C C. stations on open ground without buildings of any kind, the 10th C C S was the first chosen for the experiment, being placed at Rémy siding, near Poperinghe. He remained here for some time serving, as Major-General Sir Anthony Bowlby writes, "with great credit, a most zealous and capable officer, and a first-rate organiser." He was several times mentioned in despatches and was made a Companion of the Distinguished Service Order. Later he served on the staff, occupying various positions. For his services in the rearguard action leading up to the first battle of Ypres he received the decoration of the Belgian Croix de Guerre. At the close of the war he became personal assistant to the Director-General of Medical Services and later acted in a similar capacity to the Adjutant-General, being, we believe, the first officer of the R A M C to hold this position. For his services in these posts he received the rare distinction of being, while still a captain, gazetted Brevet Lieut-Colonel, on promotion to Major. In 1921 Lieut-Colonel Wright proceeded to India, serving on the staff at Simla and later commanding the British Station Hospital at Roorkee. Returning to England in October, 1925, he was posted D A D M S to the British Army on the Rhine, and was one of the last to leave Cologne when the army moved south to Wiesbaden. Early in the present year, however, he returned to India and had just taken up the appointment of Senior Medical Officer at the British Station Hospital Madras, when he was stricken down with appendicitis which proved, unhappily, fatal in the afternoon of June 30th. So passed away one who it is safe to say is and will continue to be mourned by a singularly large number of devoted friends.

The following note from an intimate source will recall "Wilbur" Wright to many of these:—

"A man of commanding presence he filled most doorways through which he entered and gave an impression of strength and power which was still further accentuated by his imperturbable composure. Reserved and seemingly austere on first acquaintance, his manner rapidly thawed when, as so often happened, acquaintance ripened into friendship. Gifted with a sense of humour—forms of leg-pulling particularly in his earlier days were a favourite amusement one of his most successful efforts being commemorated in the nom de corps of Wilbur by which he was almost universally known. Devoted to the army, and punctilious in attending to his duties, he yet found time to become well informed on most subjects and to develop a no mean musical talent. Geniality, modesty, and sympathy were the outstanding features in a very attractive personality. With his natural gifts and varied experiences he seemed destined for positions of still greater influence and honour than those he had already held. It was however, not to be. Death is common, it is all one in the final event of things, but in his prime, who would not mourn for Lycidas?

. . . haec .
Accipe fraterno multum manantia fletu,
Atque in perpetuum frater, ave atque vale"

ARCHIE REITH FRASER, M D ABERD

Dr Archie Reith Fraser, who died on July 10th at Plumstead Cape Province, South Africa aged 36, was educated at the Aberdeen Grammar School and studied medicine at the University where he graduated M B, Ch B in 1914, and immediately took a temporary commission in the R A M C. He was invalided from abroad after Neuve Chapelle and on recovery served at home with the 1st Scottish General Hospital and afterwards at the Scottish Command Venereal Hospital at Robroyston. He acquired a wide and varied experience of venereal work in the

MARSEILLES BRITISH MERCHANT SEAMEN'S HOSPITAL

To the Editor of THE LANCET

SIR,—In 1924 I appealed, through the press of Great Britain, for funds to complete and open the above hospital As a result of the response we were enabled to complete the building, and the hospital is now ready to receive patients A representative of His Majesty's Office of Works recently inspected it and gave a very favourable report both as regards the sums expended and the nature of the work accomplished Provision exists for 60 beds which, as things are at present, is more than sufficient for the needs of the seamen for whom the hospital has been built, and the Executive Committee have, therefore, arranged to take in private patients who may require treatment when passing through Marseilles and whose contributions will materially assist in the cost of maintenance Her late Majesty Queen Alexandra, our patroness, took a keen interest in the hospital In token of our gratitude, and with His Majesty's permission, the Executive Committee have decided to re-name it the Queen Alexandra Memorial Hospital (Marseilles) The building fund is practically exhausted and, while there is no debt, the Committee do not feel justified in actually opening the hospital without a satisfactory balance to meet the initial running expenses They are, therefore appealing for a sum of £5000, and immediately this is forthcoming the hospital will be opened, and, it is hoped and believed, satisfactorily meet a need which has long been felt by the merchant seamen who visit the port of Marseilles as well as by such travellers from the Far East and others for whom there may be accommodation

Subscriptions should be sent to Mr F C Goodenough (chairman, Barclays Bank), Hon Treasurer, Queen Alexandra Hospital (Marseilles), Barclays Bank, 54, Lombard-street, E C 3

I am glad to be able to announce that their Royal Highnesses the Duke and Duchess of York have graciously consented to become patron and patroness of the hospital, and I am authorised to say that this appeal has their warmest sympathy and support

I am, Sir, yours faithfully,
SPENCER S DICKSON,
H B M 's Consul General, Marseilles,
Chairman of the Executive
Committee

July 6th, 1926

⁂ The requirements of seamen in British and foreign ports have often been described in our columns, and we have pleasure in publishing this appeal for an institution which could do excellent work where it is urgently needed —ED L

ALTERATION OF VISION DUE TO BASAL FRACTURE OF SKULL

To the Editor of THE LANCET

SIR,—With reference to Dr Ibotson's suggestion in THE LANCET of July 3rd (p 43) that alteration of vision may follow upon fracture of the base of the skull, it should be borne in mind that it is in just this type of case that the liability exists to implication of the nerve trunks at their exit at the foramina Vision that has previously been apparently normal would, undoubtedly, tend "to be indistinct" on the development of even a relative degree of muscular imbalance from, let us say, a paresis rather than a paralysis of some of the muscles supplied by the third nerve Implication of all the muscles supplied by this nerve is by no means necessary

It should also be borne in mind that vision which before an accident has been described as normal may in reality have been very far from being orthophoric, but may have given no trouble owing to attention never having been directed to the defect, the nature of the patient's occupation, it may be, having made no call on the finer muscular movements The accident, leading to fracture of the base, may in reality have unmasked a latent defect rather than have caused the development of anything new (of course, in the case of a minus defect this is not so likely to occur) In this way an amblyopia discovered after cranial injury may be more easily explained than by postulating an actual distortion of the corneal curves to even so trifling an extent as half a diopter, as in the case cited by Dr Ibotson

I am, Sir, yours faithfully,
Manchester, July 15th, 1926 W J RUTHERFORD

Obituary.

ROBERT HUNTER STEEN, M D , F R C P LOND,

EMERITUS PROFESSOR OF PSYCHOLOGICAL MEDICINE, KING'S COLLEGE

WE much regret to record the death of Dr Robert Hunter Steen, the well-known psychiatrist, who died at Bexhill on July 12th, aged 56

Robert Hunter Steen was born in Belfast in 1870 the son of Dr Robert Steen, Ph D , and was educated at the Royal Belfast Academical Institution and Queen's University, Belfast His medical education was obtained at St Mary's Hospital, and in 1894 he graduated with honours as M B London He was house physician at his hospital, and afterwards at the Brompton Hospital for Consumption, when, having decided to take up the specialty of mental disease, he became assistant medical officer at "The Priory," Roehampton He held the post of assistant also at the West Riding Asylum, Wakefield, and at the West Sussex County Asylum, Chichester, and in 1905 was appointed medical superintendent of the City of London Mental Hospital at Dartford Here the admirable work which he did is familiar not only to his more immediate colleagues, but to all interested in psychological medicine Four years later he became professor of psychological medicine at King's College and at the time of his death, having retired from Dartford, he held the emeritus professorship

Dr Steen took the M R C P Lond in 1913 and obtained the F R C P eight years later, and during his period of office at Dartford wrote much on various aspects of asylum work and mental diseases Among those contributions to scientific literature may be mentioned papers on exophthalmic goitre, on moral insanity, on dementia præcox, on hallucinations in the sane, and on chronic hallucinatory psychosis, all the latter papers being contributed to the *Journal of Mental Science* The last essay showed very well Steen's learning as derived from actual experience and sound methods of thought The work was based upon a series of cases in which the presence of hallucinations was the principal symptom, and some of the cases could be classed as melancholia, while the development of delusion of persecution might in others lead to a provisional diagnosis of paranoia, and yet others might be classified as dementia præcox In the face of the confusion of category and nomenclature, which was greater then than now, Steen set out to show that there were hallucinatory cases which could be grouped together on a well-defined clinical entity Throughout his discussion of the differential diagnosis he recognised the difficulties of classification in the way that is now leading to a much better clinical understanding of mental symptomatology, while he prophesied that the multiplication of special out-patient departments at large hospitals, by familiarising more observers with psychological patients, would greatly improve the treatment of early disease, and that psycho-analysis would prove of service

Psychological medicine has lost in Steen a valuable thinker and worker He was a keen exponent of humane methods and spared no pains in the abolition of all that savoured of prison in the treatment of the insane, keeping the ideal of the mental hospital steadily before him, and before a large public was discussed by Colonel Lister and Colonel Coppinger, Mr Zorab, Mr. Harrison Butler, Mr Walker, Mr Coulter, and Mr Jaques

On the morning of Saturday Dr T. S Good, medical superintendent of the Oxford City and County Mental Hospital, read a paper entitled Psychology and the Eye, in which he gave details of cases where the relief of trouble caused by refraction error had had a marked effect in clearing up mental disturbances and of other cases in which no result was obtained although eye symptoms were prominent in these, but without abnormality in the eyes themselves

Mr Harrison Butler followed with an instructive paper on the signs of inflammation in the eye when examined by the slit-lamp The proceedings of the meeting concluded with a paper by Dr Margaret Dobson on the macular region as seen by red-free light Some interesting drawings of the appearance presented by the macula in both normal and diseased conditions were shown and revealed changes which could not be easily detected by other means

The annual dinner took place on the evening of July 15th in Keble College, amongst the guests being Sir Archibald Garrod and Prof J A. Gunn

Medical News.

UNIVERSITY OF OXFORD —The Theodore Williams Scholarship in Anatomy has been divided between Mr G H Bateman and Mr J H B Beal (both of University College) Mr H A Mansell (Pembroke) has been elected to the Theodore Williams Scholarship in Pathology

UNIVERSITY OF CAMBRIDGE —The following candidates have now satisfied the examiners in both parts of the examination for the Diploma in Tropical Medicine and Hygiene —

Herbert M Ayres, James L Dunlop Bandi Ethirajulu, Neil E Goldsworthy, Riad Abdel Noor Henein *Farid Hilmy, Wasfy Omar, *Trilok Chand Puri, Francis C Tibbs, and *Abdul Wahid el Wakil

* Distinguished in the examination for Part II.

At recent examinations for the Diploma in Medical Radiology and Electrology the following candidates were successful —

Part I—I Arons, Frances Dooley, H Franklyn, L Freeman, H M Grey, Elsie H Parker, and Constance A P Wood

Part II—I Arons A E I Connolly J D Dhruv, A C Dixon, H H Elliot Mollie Fisher H Franklyn Margery Freeborough H J Louw, P J McKenna, Elsie H Parker R Phillips S J Rom A C Rusack, J O P Smith, H T Stack, J G Stephens, and Constance A. P Wood.

UNIVERSITY OF EDINBURGH —The following candidates have passed the Final Examination for degrees of M B , Ch B —

Ashley G Abraham Katharine H Aitchison John B Allan, Arthur M Anderson, David Anderson Frederick P M. Anderson, Hyman E. Bernstein William W Besson, Lucia L C Black Philip W H Bleasdale, Abraham Bortz, Irene Bott, George S Broadbent George Brown, Mary A. Buchanan, George R. Burnett William D Cairns, Robert A. Cameron, John Campbell, Sine Kirstine Carlsen, Eric L Carter, John A. Chapel, James B Cherry, Robert Cormack David K. Crawford, Edith E. Cromb, Harold T Crossley, Lillie S Dickson, Maurice B D Dixey, George S N Dow, David C Dunlop Derrick M Dunlop Annie C Easterbrook, James A Elliot, Dorothy Ellison Robert Everett Isabelle B S Flett Arthur D Frazer Patrick C Garson, Anne Gibson Hubert J Gibson, Robert S Gilchrist, James C Gilroy Frank O Graham, James D A. Gray, Evelyn F Hartley, Vincent L P Hayes, Lillian A Hayward James R. Henderson, Muriel G Henderson, William R. Henderson Margaret R. Henry, Jane A Horne Jessie Horne Leonard C Huggins, Margaret H Hunter Jess Marian Ireland Stanley Jackson May Jones (with distinction), Mohamed C M Kaleel Martha Keith Alfred L. Kiow, Pauline Klenerman, John Lamb William L Lamb, Noel A Large, Martha J Lennox, Luke N Liang Julius Lipetz John Litt James L. Lochhead, Maurice L Lucas Robert B Lumsden John Macdonald Cecil T. M'Inerney Donald C Mackenzie, Archibald J M'Kinlay, Margaret I M'Kinlay, William M M'Lellan Margaret G M'Millan Robert L. M'Morris Margaret M'Murray George H Macnab, George R M'Nab James A S Macpherson Saadallah Madwar Samuel Layinka Ayodeji Manuwa Robert M Marshall, Hamish F Masson Aileen E. Mathers David M. W Maxwell (with distinction), William B Millar Gavin W Milroy, James E. Monro (with distinction), Susannah S. Murdoch, Ranald M. Murray-Lyon Honor O Newell Douglas N Nicholson, John S Oliphant Nathaniel Taiwo Olusoga James P D Parsons Andrew Patrick, Kumara Nilkanda Pillai, Neelakanda Palpoo Pillai, Richard E. H Pulipaka William M Quin, Syed Abdur Rahman, Frank M'Lean Richardson Frances A Roberts, John B Rolt, Archibald Ronald, William R. Russell, Vidya Vati Saberwal Simon Tsoi Mook-Sang, John M. Sanson, Richard G A Savage Charles M Scott, William S Shearer, William Simpson, Evan Siung, Angus D. Smith, Francis A. M'C Somerville Michael Stein, Leo J. Stone, Thomas M Strang, Ian N Sutherland, Harry Sweidan Margaret E N Tait, Cyril G K Thompson, Dorothy A. S Thompson, William E Thompson, Violet B Tulloch, Lionel Turiansky, Robert L Turner, Frank Walker, Victor G H Wallace, John H Watson, David Wilkie, Philip M Wood, Thomas V Woods, Harold R. Worth, Helen A. Wright, and David J Young

ROYAL COLLEGE OF SURGEONS OF EDINBURGH — At recent examinations out of 22 candidates entered the following five have passed the Final Professional Dental Examination and have been granted the Diploma L D S R C S Edin —

Margaret Leslie, Kenneth Stewart, Richard V P Campbell, Hugh Linn, and Max Nathan

ROYAL COLLEGE OF SURGEONS OF ENGLAND —At a meeting of the Council held on July 8th the following were elected Hunterian professors for the ensuing collegiate year Sir Arthur Keith (six lectures on Recent Researches carried out in the Museum), Mr Zachary Cope (Shock and Collapse in Acute Abdominal Disease), Mr J. E H Roberts (The Diagnosis and Treatment of Intrathoracic Tumours), Mr E M Cowell (Recent Advances in the Surgery of Hernia), Mr A. H Southam (The Pathology and Treatment of the Retained Testes in Childhood), Mr W B Williams (The Importance of Toxæmia Due to Anaerobic Organisms in Intestinal Obstruction and Peritonitis), and Mr J Howell Evans (Testicular Tumours of Congenital Organs) The following were elected Arris and Gale lecturers Mr R St Leger Brockman (The Cause of Toxæmia and Death in Acute Obstruction), Dr Hildred Carlill (The Simulation of Surgical Affections by Hysteria); and Dr Alfred Piney (Hyperplasia and Neoplasia in Lymphatic Tissue) Mr C E Shattock was elected to the Erasmus Wilson lectureship and will give six demonstrations on pathology Sir Arthur Keith, as Arnott demonstrator, will give six demonstrations on the contents of the Museum. Mr Richard H. Burne was elected physiological curator, Mr C F Beadles pathological curator, and Sir Frank Colyer honorary curator of the Odontological Collection

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION —The Fellowship of Medicine announces that the last of the demonstrations arranged for this session will be given by Mr Dorrell at the Royal Eye Hospital, Southwark on Friday, July 30th, at 3 P M This will be open to members of the medical profession without fee Attention is directed to the formal lectures at the North-East London Post-Graduate College Tottenham which are delivered at 4 30 P M throughout the week and are open to members of the Fellowship of Medicine Subscription to the Fellowship is 10*s* per annum, which includes a copy each month of the *Post-Graduate Medical Journal* A late afternoon course of instruction in neurology will be given at the West End Hospital for Nervous Diseases throughout the week at 5 P M The fee for the course will be £1 1*s* and it will continue until August 12th Owing to unforeseen circumstances the intensive course to be given at the Brompton Hospital for Chest Diseases has been cancelled The entire clinical work of the hospital will, however, be available to graduates daily throughout the month on payment of 1 guinea. From August 18th to 28th the Queen's Hospital for Children will hold an all-day course covering instruction in all departments of the hospital The hospital staff are kindly providing luncheon and tea The Queen Mary's Hospital has arranged an intensive brush-up course from August 23rd to Sept. 4th for the benefit of those who wish to refresh their knowledge in up-to-date hospital practice The Fellowship can accommodate graduates with practical courses in anæsthetics and weekly practical courses in obstetrics and child welfare at the City of London Maternity Hospital The fee for the latter is £2 2*s* a week and personal application must be made at the office of the Fellowship Full particulars and details of the various courses may be had from the Secretary of the Fellowship at 1 Wimpole-street, London, W 1

RESIGNATION OF PROF MATTHEW HAY —The University Court of the University of Aberdeen has accepted with regret the resignation of Prof Matthew Hay from the Chair of Forensic Medicine, and has passed a minute of appreciation of his valued services to the University, extending over the long period of 43 years The minute sets forth the services of Prof Hay "The indebtedness of the whole University to his ability and assiduity both in teaching and administration, to his patience and impartiality, and his sagacity and foresight in the supervision of the finances of the University, cannot be overestimated" army, and in 1920, having taken the M D degree with distinction, he went to Pretoria as a venereal specialist to the Union Government of South Africa. His health soon broke down, but after resigning this post he was appointed university lecturer in venereal diseases at Cape Town. He was intensely keen on this work, and besides a monograph on Gonorrhœa, published a number of papers in the medical journals, all his writings being characterised by originality and clearness of outlook. Those who did not always agree with him could not plead that they did not follow his arguments. He was secretary to the Cape Town branch of the British Medical Association, and Dr Alfred Cox writes: "He was a really brilliant personality and one could not meet him even casually without having a strong impression left. he was a white man all through."

Dr Fraser was also an accomplished artist. He leaves a widow and two daughters.

OXFORD OPHTHALMOLOGICAL CONGRESS.

Under the Mastership of Mr Philip H Adams, the sixteenth meeting of the Oxford Ophthalmological Congress took place at Oxford on July 14th to 17th. No meeting was held last year owing to the Convention of English-speaking Ophthalmological Societies, but with this exception the congress has met annually since its inception in 1910. The membership, which in that year was 181, has steadily increased to 380 at the present time. As in past years, the proceedings took place in the Department of Human Anatomy through the kindness of Prof Arthur Thomson, and members were again indebted to Keble College for hospitality.

The congress was opened on the 15th by a short address of welcome by the Master, followed immediately by a discussion on

Sympathetic Ophthalmia

Mr. Malcolm Hepburn opened the discussion by outlining the history of the treatment of the condition during the past 50 years and comparing this with present-day methods. He said that owing to the dread of sympathetic ophthalmia occurring even many years after the injury, probably many eyes had been excised in the past which might have proved useful. The general trend of opinion now, however, was against the likelihood of sympathetic trouble appearing after a lapse of years, and it was to those cases of cyclitis developing within a few months after the exciting cause that Mr Hepburn directed attention. Not all such cases were of the nature of sympathetic ophthalmia, and some scientific method should be aimed at whereby a cyclitis of sympathetic origin, could be differentiated from one due to other causes. Mr Hepburn suggested that not all eyes which manifest keratitis punctata, even though of sympathetic origin, should be excised, and that many eyes with keratitis punctata following injury or operation should be operated on for the relief of symptoms. He emphasised the value of the differential blood count, a large excess in percentage of the large mononuclear cells with decrease in the polymorphonuclears was a valuable guide in deciding the line of treatment to be taken. Mr. S H Browning presented the bacteriological side of the subject dealing chiefly with the question of the differential blood count. Cases were quoted in which a change in the blood count had preceded any other signs of sympathetic ophthalmia and had determined the line of treatment to be followed. He discussed treatment by arsenic preparations of the "606" type, and also the anaphylactic theory of the disease. Dr. G E de Schweinitz (Philadelphia) followed with a special reference to the work recently done by Verhoeff and presented at the last meeting of the American Ophthalmological Society. Seven cases of sympathetic uveitis were treated by Verhoeff by frequent subcutaneous or intramuscular injections of diphtheria antitoxin in large doses. In four of the seven a remarkable improvement in vision was obtained, but the effectiveness of the treatment was most striking in causing a rapid subsidence of the inflammatory condition. Mr Harrison Butler pointed out the value of the slit-lamp in detecting the earliest signs of the disease and mentioned illustrative cases.—Mr Russ Wood described two cases in each of which the reaction to tuberculin tests was positive.—Prof Emile de Grósz (Budapest) stated that in the past 50 years 150 cases of sympathetic ophthalmia had been treated at the No 1 Eye Hospital at Budapest, making 28 per cent. of the total patients seen. Ten per cent. of these had followed operations, most of which had been performed elsewhere. In his view repeated operations on injured eyes increased the risk of sympathetic trouble. He was convinced that the inflammation was metastatic in nature.—Lieut.-Colonel H Herbert referred to the iris-inclusion operation for glaucoma and the supposed risk of sympathetic ophthalmia.—Mr J Gray Clegg spoke on the occurrence of the trouble after evisceration.—Lieut.-Colonel A E J Lister commented on the rarity of the disease in hot dry climates.—The following also took part: Mr A. F MacCallan, Mr A Greene, Dr Arnold Verrey (Lausanne), Mr T C Summers, Mr R J Coulter, Mr N C Ridley, Mr A. Zorab, and the Master. Mr Hepburn and Mr Browning replied.

Demonstrations in the Scientific Museum

The afternoon was given up to demonstrations in the Scientific Museum. Colonel Herbert demonstrated an iris inclusion operation for glaucoma, Dr G Young showed statistics on ophthalmometry, Colonel Lister presented tables showing the weights of 180 cataractous lenses with details as to patients' weight, age, blood pressure, &c.—Dr Thomson Henderson showed microscopical specimens of the ciliary region in mammalia and demonstrated his apparatus, showing the mechanism of accommodation.—Mr Tomlinson demonstrated his light-sense test for the light-adapted eye.—Lieut.-Colonel W V Coppinger showed (a) a prothesis of crude Indian manufacture which had cut through the lid of the wearer, and (b) prints of the plans of the new Calcutta Eye Hospital.—Dr Burdon Cooper demonstrated Pulfrich's phenomenon and brought forward evidence that the explanation was one connected with accommodation rather than with dark-adaptation.

In an adjoining room the most recent ophthalmic apparatus and instruments were on exhibit by a number of well-known firms.

The Doyne Memorial Lecture.

On Friday morning papers were read by Dr Young on (a) Can an amblyopic eye recover good vision, and (b) a suggestion as to the cause of the invisibility of the retinal vessels and explanation of Purkinje's phenomenon. The former referred to the case of a man of 60 with an amblyopic eye associated with internal strabismus who had lost the vision of the good eye from embolism; the vision of the amblyopic eye improved in a year from less than 6/60ths to 6/6ths. Dr Marion Gilchrist presented some interesting medico-legal cases. The Doyne memorial lecture was delivered by Dr Thomson Henderson, of Nottingham, on the Anatomy and Physiology of Accommodation in Mammalia. Some original theories on the physiology of accommodation were put forward whilst the anatomy of the ciliary region was shown in a valuable series of slides and drawings from various mammalia, including man. At the conclusion of his lecture Dr Henderson was presented with the Doyne memorial medal for the year.

In the afternoon Lieut.-Colonel H Smith presented a review of the various methods of performing intracapsular extraction of cataract and described in detail his own latest method of expression, the outcome of his work during the past winter in India. The paper

STANLEY HOSPITAL, LIVERPOOL.—At the fifty-ninth annual meeting it was stated that during 1925, for the first time in its history, the hospital's income equalled the expenditure There is still, however, a debit balance of over £10,000

A YEAR'S WORK AT GUY'S HOSPITAL —The report for 1925, which has just been issued, contains a mass of interesting and important matter In the department of finance it is pointed out that annual subscriptions and donations are apparently stationary at less than £12,500, about 7½ per cent of the total expenditure, and "a small recognition of the hospital's service to the public" The bicentenary appeal for a capital sum to relieve the hospital and medical school of debt has produced £86,500, considerably more than half of which has come from what may be called domestic sources—governors, medical, surgical, and dental staff, old Guy's men, the administrative staff, Past and Present Nurses' League, and the Ladies' Association The income and expenditure account has been balanced by appropriating £18,200 from the Bicentenary Fund Patients' voluntary contributions amounted to £6000, payments from the Hospital Saving Association on behalf of its working-class members increased from £1690 to £5000 Ordinary expenditure has increased by nearly £10,000 The report records that in no previous year of its history has the hospital "admitted so many patients, relieved so much suffering, or made such advances in the knowledge and treatment of disease" Since 1921 the increase in the number of patients passed through the wards has amounted to more than 1000 a year The cost of each occupied bed was £207 10*s* 6*d*, and since some 400 new out-patients are dealt with every working day the governors will shortly be confronted with the need for reorganising and enlarging the out-patient department The department of deep X ray therapy possesses only one machine, and there is urgent need for two additional installations A nurses' representative council has been established, the members of which are selected by ballot from among the nurses of each year, and some useful reforms have already resulted A more liberal diet has been supplied to the nursing staff There has been no lack of applicants for training as nurses, and they have shown a notable record of success in the State examinations, the whole of the candidates for the certificate of the C M B were successful Sympathetic reference is made to the death of Dr G H Hunt, physician to the hospital, whose work, it is remarked, "had marked him out as a scientific clinician who would some day have ranked among the most distinguished physicians of his time"

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 10TH, 1926

Notifications —The following cases of infectious disease were notified during the week —Small-pox, 128 (last week 135), scarlet fever, 1374, diphtheria, 853, enteric fever, 85, pneumonia, 590, puerperal fever, 37; cerebro-spinal fever, 9, acute poliomyelitis, 5, acute polio-encephalitis, 1, encephalitis lethargica, 37, dysentery, 20, ophthalmia neonatorum, 115 There were no cases of cholera, plague, or typhus fever notified during the week

Deaths —In the aggregate of great towns, including London, there were 3 (1) deaths from enteric fever, 18 (0) from measles, 6 (0) from scarlet fever, 27 (3) from whooping-cough, 17 (2) from diphtheria, 48 (8) from diarrhœa and enteritis under 2 years of age, and 35 (8) from influenza. The figures in parentheses are those for London itself

THE LANCET SUBSCRIPTION RATES

		£	s	d

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

University of London Bill

THE University of London Bill passed the Report stage in the House of Lords on Tuesday, July 13th

Mental Defectives Bill

A new Bill introduced by the Government amending the law with regard to mental defectives was introduced and read a first time in the House of Lords on Thursday, July 15th

The Royal Assent was given to the Bethlem Hospital Act on Thursday, July 15th

HOUSE OF COMMONS

WEDNESDAY, JULY 14TH

Invaliding Tests in the Navy.

Mr **HORE-BELISHA** asked the First Lord of the Admiralty to what causes the Admiralty attributed the fact that 95 per cent of those invalided from His Majesty's Navy were denied pensions on the ground of non-attributability, seeing that every one of these men had passed a severe test of physical fitness on entering the service —Mr **BRIDGEMAN** replied A disability is not regarded as attributable to the service when it is due to ordinary conditions of service such as might equally have arisen had the invalided rating been engaged in a civilian occupation, or when it is due to conditions of health that are normally constitutional in origin Every officer or man is subjected on entry to a thorough physical examination, but from time to time disabilities of an obscure or latent character are bound to escape detection Moreover, the mere passage of time may produce a condition of health which, although it does not necessarily unfit a man for civil occupation renders him unsuited to a fighting service where the highest state of physical fitness is required and his invaliding then becomes necessary I would remind the hon Member that pensions are granted in non-attributable cases where the invalided man has a certain minimum period of service

Physical Tests for Post Office Employees

Captain **GARRO-JONES** asked the Postmaster-General whether there remained any appointments under his control which were not open to ex-Service combatant officers or men on the ground that, though in good health, they had not the physical strength or height necessary to fulfil their duties —Sir W **MITCHELL-THOMSON** replied An ex-Service man is given preference for Post Office employment wherever possible, but it occasionally happens that a candidate does not reach the required standard of physical fitness—modified I may say, in the case of disabled ex-Service men—or is below the minimum height fixed by definite regulations

THURSDAY, JULY 15TH.

THE MIDWIVES AND MATERNITY HOMES BILL

On the order for the consideration of the Lords amendments to the Midwives and Maternity Homes Bill

Lieut -Colonel **FREMANTLE** moved that the House do agree with the Lords amendment to Clause 1 providing that the clause should not apply in the case of a person who while undergoing training with a view to becoming a duly qualified medical practitioner, or a certified midwife, attended a woman in childbirth as a part of a course of practical instruction in midwifery recognised by the General Medical Council or by the Central Midwives Board He explained that this amendment had been inserted as necessary to safeguard the work of medical students under tuition Although they were not qualified men they were doing useful work under proper safeguards in training schools

The Lords amendment was agreed to

Lieut -Colonel **FREMANTLE** moved that the House do agree with the following amendment to Clause 11 inserted in the Lords —

> (1) A local supervising authority may grant exemption from the operation of this part of this Act in respect of (*a*) Any hospital or other premises for the conduct of which a duly qualified medical practitioner resident therein is responsible or (*b*) any hospital or institution not carried on for profit and not used mainly as a maternity home
>
> (2) A local supervising authority may at any time withdraw an exemption granted by it under this section.
>
> (3) Any person who is aggrieved by the refusal of local supervising authority to grant exemption under this section in respect of any hospital premises or institution or by the withdrawal of any such exemption previously granted by the authority may appeal against the refusal or withdrawal to the Minister of Health and the Minister after considering the matter shall give such directions therein as he thinks proper, and the authority shall comply with any directions so given

He said that this amendment was necessary in order to allow certain social welfare institutions which occasionally took in maternity cases incidental to their work to escape

Royal Society of Medicine—Although the society's house will be closed as usual during August for cleaning, the library will be open on week-days from 11 A M to 6 P M, except on Saturdays, when it will close at 1 P M

Victoria University of Manchester — The following awards have been made Sheridan Delepine Fellowship in Preventive Medicine M A Omar, Robert Platt Physiological Scholarship, Cæcilia E M Pugh, Prof Tom Jones Exhibition in Anatomy, Dorothy A Geiler

Trinity College Dublin Post-graduate Course—The School of Physics has completed arrangements for a post-graduate course which will begin on Sept 13th and finish on Oct 2nd Classes will meet in the Medical School of Trinity College and in several of the Dublin hospitals

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on July 6th, Surgeon Vice-Admiral Sir Joseph Chambers, Medical Director-General of the Navy, in the chair, the sum of £55 was distributed among the several applicants

New Hospital for Lyme Regis—The cottage hospital at Lyme Regis, which is in the heart of the town, has long been unsuitable for its purpose, but it has been difficult to replace it The obstacles have now been removed by the generosity of the Rev G F Eyre, who has presented to the hospital the large residence known as Herne Lea

Hospital for Diseases of the Heart and Lungs—The Prudential Assurance Company is providing £3250, the cost of building a laboratory for pathological research work at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park This is the only hospital in the East End which deals solely with affections of the heart and lungs

The late Dr H Edmondson—Dr Herbert Edmondson, who died at his home at Reedley on July 13th, had practised for nearly 25 years in the Burnley district as an aural and ophthalmic surgeon Educated at Repton, Cambridge and the London Hospital, Dr Edmondson graduated M B, B Ch in 1901 He was honorary ophthalmic and aural surgeon to the Burnley Victoria Hospital and to several other institutions in the neighbourhood

Dinner to Dame Mary Scharlieb—A dinner, organised by the London Association of the Medical Women's Federation, was held at the Welbeck Palace Hotel, on July 15th, in honour of Dame Mary Scharlieb The President, Dr Christine Murrell, regretted the absence of many friends who had been unable to attend at such short notice The health of the principal guest was proposed by her old friend and fellow-student, Dr Jane Walker, who spoke warmly of her personal qualities and professional standing Dame Mary Scharlieb was over 40 years of age before she ever had a scalpel in her hand, and now, at 81, she was still operating with unimpaired judgment and skill Dr W Carr paid tribute not only to the outstanding surgical ability of Dame Mary Scharlieb, but to her high character, without which her other qualifications would have been useless, if not even dangerous All her friends would rejoice at the national recognition of her services, which were the more valuable because love of her fellow-creature had prompted them Lord Riddell pointed out that the British virtues of courage, pertinacity, and ability were combined in her with charm of manner and an unusual and enduring vitality Sir Alan Anderson praised the pioneer spirit that was an inspiration to younger women who were attempting to open up other professions to women Mrs Scharlieb's example and reputation could not fail to help to allay prejudice against women workers in every sphere Lady Barrett, speaking as dean of the London (R F H) School of Medicine for Women, spoke of the pride of all members of the school in the honour that had been conferred on Dame Mary Scharlieb There had been great excitement, and in certain quarters some misgivings, when a previous honour had been paid her—that of being the first woman to be appointed on the staff of any general hospital in this country Dame Mary Scharlieb had soon silenced any doubts by the swiftness and skill of her operative technique, and her unfailing courtesy to the sisters in charge of the wards In reply, Dame Mary Scharlieb said that if life were a quest for happiness, she had discovered how to achieve it, in the love of God and of her friends Among the guests present, other than the speakers, were Sir John Rose Bradford and Sir James Berry

Pensions for Hospital Officers and Nurses—Definite steps have now been taken by 69 of the hospitals in London to start a general contributory system of pensions for hospital officers and nurses on the lines of the draft scheme published by King Edward's Hospital Fund for London in November last It is anticipated that the system will be in operation on or before Jan 1st next

Small-pox and Poor-law Institutions—A circular has been issued by the Ministry of Health drawing the attention of guardians to the need for care in the admission to Poor-law institutions of persons who may be suffering from small-pox Unrecognised cases of this disease, it is stated, have been the means of spreading infection in such places, and attention is drawn to the regulation that before admission every applicant must be examined by the medical officer

A **Committee** has been appointed by the Privy Council to consider whether any modifications are desirable in the Poisons and Pharmacy Acts The members are Mr E Mitchell-Innes, K C (chairman), Mr L G Brock, Sir Malcolm Delevingne, Mr F W Gamble, Sir W Graham Harrison, Sir Donald MacAlister, M D, Mr E T Neathercoat, Mr Colin Smith, Mr G Stubbs, Sir William Willcox, M D, and Mr A E Young The secretaries are Mr M D Perrin, of the Home Office, and Dr E W Adams, of the Ministry of Health

Beit Memorial Fellowships—A senior Fellowship (£600 per annum) has been awarded to Ernest Basil Verney, and fourth-year Fellowships (£400 per annum) to William Kershaw Slater, Harold John Channon, and John Maurice Hardman Campbell The following have been elected to Junior Fellowships (£350 per annum) —

Richard James Lythgoe, M A, B Ch Camb, Sharpey Scholar University College, London, who will investigate the electrical reactions of the optic and auditory nerves

Frank Macfarlane Burnet, M D Melb, temporary assistant, the National Collection of Type Cultures, Lister Institute, London, who will study bacteriophage in relation to the treatment of enteric bacillary infections

John Glover Hugo Frew, M Sc Birm, working at the Research Hospital, Cambridge, who will investigate the physiology of the blow-fly

Maurice Walter Goldblatt, M D, B Sc Belf, working at St Thomas's Hospital, who proposes to continue his study of (1) the relation between ketosis and alkalosis, (2) the fate of the two terminal carbon atoms in the fatty acid chain during the hypothetical β oxidation process, and (3) the rôle of insulin in fat metabolism

James Tutin Irving B A Camb, now junior demonstrator in Biochemical Department, Cambridge, who will undertake research in the Biochemical Department, Oxford, on the metabolism of carbohydrates and allied compounds in the animal body

John Gower Stephens, M B, M S B Sc, Sydney, now working at the Physiological Department, Cambridge, who intends to make a further study of the functions of the spleen by the method of window observation

Barnet Woolf, B A Camb, working at the Sir William Dunn Institute, Cambridge, who will undertake a comparison of some chemical reactions induced by resting bacteria with those induced by animal tissues

Payment of Panel Doctors—The system by which panel practitioners are paid by attendances is confined to the Manchester and Salford areas and to the Isle of Man, all the rest of the country having adopted the capitation system In order to discover whether Manchester doctors want to fall into line, the Manchester Medical (and Panel) Committee has been taking a postal vote of all insurance practitioners, of whom there are about 400 in the Manchester and Salford area The total number of insured persons who now come under the attendance system (in the Manchester, Salford and the Isle of Man) is about half a million, and some 14,000 doctors are in panel practice in the area Insured persons who come under the capitation system in other parts of the country number about 14½ millions In its report the committee discusses the differences between the two systems The amount of money available for distribution is the same, calculated on the number of insured persons in each area Under the attendance system, no doctor working single-handed can receive more than £1125 Under capitation a doctor's list may not exceed 2500 insured persons A large amount of clerical work is entailed by the attendance system, as compared with the capitation system Under the attendance system, the number of services rendered to each insured person in Manchester was 4 38 for 1923, and in all other areas 3 75 for the same year The actual payment per service per insured person in Manchester for 1923, worked out at 1*s* 11*d*, and in some other areas at 2*s* 7*d* As a result of the postal vote Salford insurance practitioners have decided to fall into line with the general rule in the country—i e they have declared themselves in favour of the capitation basis members of the junior division of the Officers' Training Corps from attending camp in the previous year

TUESDAY, JULY 20TH

Public Health in India

The House went into Committee of Supply, Captain FITZROY in the chair.

On a vote of £47,401 for the salaries and expenses of the India Office

Earl WINTERTON, the Under Secretary for India, referred to the decision of the Government of India to extinguish their exports of opium, except for medical and scientific purposes, by progressive annual reductions The Government of India had decided to reduce the exports in ten years, when the process would be complete. The total exports for 1926 would be reduced by 10 per cent in each subsequent year, so that the last export would take place in 1935 The bulk of the recommendations of the Lee Commission with regard to the Civil Service, including those of a financial character, had been implemented. A decision in the case of almost all officers appointed by the Secretary of State in Council had been reached and most of the recommendations of the Government of India and the local governments in respect of officers appointed by them had been received and were being considered The rest were expected shortly All possible steps to expedite a decision were being taken. The Public Services Commission had been appointed and the chairman had already gone to India while the commission would meet on October 1st. The position in regard to recruitment for the Indian Services continued to improve in a satisfactory manner The entries for the Civil Service examination to be held next month showed a total of 183 against 143 last year.

Sir GEOFFREY BUTLER said that there was very much that could be done by British people in this country and in India attached to the Government to help on progress in regard to the various transferred subjects The statement one sometimes heard and the assumption one sometimes encountered that the subjects transferred to the Provincial Governments were inadequately administered was one of which there was no proof But looking at these scientifically transferred services from the point of view of the Indian public, Indian public officials, or scientific experts, no one would contemplate with equanimity the severance or isolation of their activities from the best and most modern Western thought. In the medical, scientific, industrial and agricultural research fields it would be a thousand pities if they found that they had put these transferred services in water-tight compartments Therefore, he would like to know what relation existed between the scientific and technical activities of the Government of India and those of the Provincial Governments What, for example, were the relations between the central officials and the various technical officials in the public health departments of the provinces? Was the central organisation going to fade out of the picture as was the case to some extent at Washington? One could not exaggerate the importance of scientific work in the future development of India. We had won India by the sword, and we wanted to keep her for our commerce, but we must woo her by means of scientific methods India was a paradise for those engaged in scientific research. Anyone who wanted to conduct experiments in botany, physiology, into various forms of disease, and so forth, could not wish for a better field of work. He suggested that facilities should be given in our universities for students from India who came here to take up scientific research.

The Vote was agreed to

Suspension of Meals for School-Children in Scotland.

Mr THOMAS KENNEDY asked the Secretary for Scotland whether he was aware that during the summer holidays, extending over seven weeks, the Clackmannanshire education authority has decided not to continue the provision of meals for necessitous children on the ground that the authority was under no obligation to provide meals except when the children were actually in attendance at school, whether he proposed to sanction this action on the part of local education authorities, and if not, whether he proposed to take any steps to ensure that meals were provided during the vacation.—Sir J GILMOUR replied I have no information at all regarding Clackmannanshire and such information as has reached me regarding Ayrshire suggests that the hon. Member is under a misapprehension as to the decision reached by that authority On the general question however, I may remind him of the legal position as stated in Circular 67, issued under the instructions of my predecessor in office Education authorities in Scotland have no general powers of feeding, but they have a duty to deal with particular cases and provided that the circumstances of a case come within the provisions of the statute this duty would not appear to be affected by holidays It is only if and when there is reason to believe that any authority is neglecting that duty, that it will be open to me to consider what action can appropriately be taken.

Communications with the Shetland Islands

Sir ARCHIBALD SINCLAIR asked the Under Secretary to the Scottish Board of Health whether, in view of the need, particularly on the ground of public health, for the improvement of communications between the island of Stroma and the mainland, the Government would consider experimenting with the installation of low-power wireless telephony on the duplex system on this island—Sir J. GILMOUR replied. The establishment of communication by wireless telephony between the island of Foula and the mainland of Zetland for medical service purposes is under consideration at present Should the arrangements which it is hoped to make in that instance prove successful and not unduly expensive I shall be glad to consider whether assistance can be given from the Highlands and Islands (Medical Service) Fund towards the cost of similar arrangements for the other islands to which the ordinary telegraph and telephone services do not extend

Dust-shoot Nuisance at Purfleet

Mr. LOOKER asked the Minister of Health if he was aware of the nuisance and the menace to the health of the neighbourhood caused by the dust-shoot at Purfleet, and if he would take steps to see that this nuisance was not continued and that no fresh dust-shoots were allowed to be created—Sir KINGSLEY WOOD replied. An inspection was made some two years ago of the two tips to which my hon. friend refers and that inspection did not disclose any nuisance or menace to health. My right hon friend has, however, directed that a fresh inspection shall be made in the immediate future.

Houses Built of Concrete and Special Materials.

Mr HERBERT WILLIAMS asked the Minister of Health the number of houses completed during the 12 months ended March 31st, 1926, which were constructed of materials other than ordinary bricks and natural stone—Sir KINGSLEY WOOD replied. Returns from local authorities of houses built with State assistance show that during this period approximately 10,000 houses constructed of concrete or by other special methods were completed Statistics are not available for houses built without State assistance

Tuberculosis Dispensaries.

Colonel DAY asked the Minister of Health what steps are being taken by his department with a view to the greater utilisation of the opportunities provided by the tuberculosis dispensaries—Sir KINGSLEY WOOD replied My right hon. friend is not clear what further use of the tuberculosis dispensaries the hon. Member has in mind These dispensaries are provided by the local authorities and my department have always encouraged their full use as centres for diagnosis, observation, and special forms of treatment.

Increasing Cost of Working-class Houses

Viscountess ASTOR asked the Minister of Health whether officials of his department were inquiring as to the reasons for the increasing costs of working-class houses; and if so, to what causes was the continuous rise attributed—Sir KINGSLEY WOOD replied A constant watch is kept by my right hon. friend's department upon the trend of house-building prices An investigation of the reasons for the rise in building costs during the past two and a half years, which is approximately 11 per cent, shows that a rise of wages accounts for from 2½ per cent to 5 per cent., according to district, and increases in the prices of materials account for about 4 per cent The remainder of the rise in costs is probably partly due to the increase in the number of houses let in contracts, and in my right hon friend's opinion the existence of the subsidy may have contributed something in this direction

Nursing Homes for the Poorer Middle Class

Major AINSWORTH asked the Minister of Health if his department had any record of the extension of nursing homes or institutions for the poorer middle class for the use of which payment was made on a modest scale; and whether he could take any action to stimulate such provision.—Mr NEVILLE CHAMBERLAIN replied. The answer to the first part of the question is in the negative As regards the second part while I appreciate the need for accommodation of this kind, its provision is a matter for local initiative and there are no funds at my disposal from which assistance can be given

R A M C and Dental Corps Officers

Sir L. WORTHINGTON-EVANS (Secretary of State for War) informed Colonel Clifton Brown that the number of officers not holding permanent regular commissions still employed with the Regular Army on July 1st was 152 which included Royal Army Medical Corps 35, and Army Dental Corps 60.

inspection where the local supervisory authority thought it could safely be done He thought it would appeal to all members of the House when they realised that there were certain homes known as rescue homes, and other places of that sort, which occasionally had cases of women who gave birth to children They came to those homes and were properly looked after, but it was of the essence of the good work of those institutions that there should be no publicity about it It was especially in connexion with the Salvation Army that they had been approached Obviously there would be some difficulty unless the matter were left to the judgment of the proper authority The local supervisory authority was therefore given power to exempt in such cases

Mr A. V **ALEXANDER** said that the hon Member must know that an amendment of this kind was very controversial The principle involved was of very great importance A large number of the maternity cases which were likely to be dealt with in this class of home were cases from the working class, and the amendment was not all in the interest of working-class mothers who might be confined in institutions of that kind He suggested that in view of the strong feeling likely to be aroused that the amendment might be withdrawn in order that the House might have time to consider it

Dr **DRUMMOND SHIELS** said in regard to the first amendment he had nothing to say, he thought it was quite necessary. But in regard to this one, while he was in general sympathy with it, he thought it required a little consideration On the whole there was an effective safeguard in the fact that the inspecting authority would have to be satisfied of the bona fides of any hospital or similar institution before exemption was given But he would like the hon Member to consent to another safeguard—namely, that the exemption given should not extend for more than 12 months

The **SPEAKER** I take it that the hon Member is objecting If that be so, as it is after 11 o'clock the debate must stand adjourned.

The further consideration of the Lords' amendments to the Bill was adjourned

The Death in Bedford Prison

Mr **HAYES** asked the Home Secretary whether he was aware that the governor of Bedford prison advised the prison doctor on several occasions on and after May 19th to remove prisoner Russell to a hospital cell and inform the relatives of the prisoner's serious illness, that this advice was not acted upon, that the doctor stated that the man was not seriously ill and would be all right in a day or two, that the governor reported to the Prison Commissioners that he was not satisfied that the doctor had done all that could have been done for the prisoner, whether these points were considered at the Home Office inquiry, and whether the Prison Commissioners took into account, when submitting their recommendations to him, the 36 years of unblemished record of the governor and his consistent advocacy for many year of prison and penal reform —Sir **WILLIAM JOYNSON-HICKS** replied I am very sorry to have to answer questions which compel me to go into details concerning the degree of blameworthiness of an officer who, apart from this painful incident, had a long record of valuable service to his credit, and I will be as brief as possible Every point that could be urged in his favour was considered at the inquiry, and every factor was taken into consideration by the Commissioners and by me, but the responsibility of the governor of a prison for what goes on under his management must be recognised, and I felt that it was my clear duty after what had happened in this case to take the course that I announced to the House a fortnight ago

Motor Bicycles as Cause of Street Accidents

Mr **WARDLAW-MILNE** asked the Home Secretary whether his attention had been drawn to the large number of motor accidents, particularly in connexion with motor bicycles, which were now taking place, and whether, in view of this, he would instruct the police authorities to prosecute more rigorously the riders of motor bicycles who were travelling at very high speeds, in preference to instituting prosecutions against motor-car drivers who, under reasonable conditions of traffic, drove their cars at a speed which slightly exceeded that laid down by law —Sir **WILLIAM JOYNSON-HICKS** replied I can only say that the police will continue to do all they can to check the driving of both motor-cars and motor-cycles at speeds which are dangerous to the public

Swimming for School-children.

Colonel **WOODCOCK** asked the President of the Board of Education if he would consider instituting a compulsory course of swimming for school-children, after passing a medical examination, as a definite part of the school curriculum where facilities for swimming were available, and if he was aware of any education committees in the country who had already taken steps for systematically teaching the art of swimming to the scholars —Lord **EUSTACE PERCY** replied I think my hon friend underestimates the work already being done A large number of authorities already prescribe systematic courses of instruction in swimming and, in general, I do not believe that it is necessary or desirable that the Board should issue detailed directions to authorities in regard to curriculum

MONDAY, JULY 19TH

Veterinary Inspection of Imported Meat

Sir **ROBERT THOMAS** asked the Minister of Agriculture whether he was aware that the steamer *Cambrian Countess* had just delivered 250 head of cattle from the Argentine at Zeebrugge, and that a British veterinary surgeon, appointed by the Ministry of Agriculture, had subjected these animals to examination and had certified them to be free from disease, that the animals had been slaughtered and sent to the London market, via Harwich, as fresh meat at considerably less than home-produced meat, and, having regard to the need of reducing the cost of living, whether he would permit similar regular shipments subject to the same veterinary inspection —Mr **GUINNESS** replied The vessel in question had sailed from Argentina before the date in which the Importation of Carcases (Prohibition) Order came into force In view of the special circumstances of the case carcases from this cargo were allowed to enter the country subject to a special veterinary examination of the animals both before and after slaughter I regret that I cannot see my way to accede to the suggestion contained in the last part of the question The importation of live animals from South America is prohibited by order on account of the prevalence of foot-and-mouth disease in some parts of that continent, and the establishment of a slaughter house at Zeebrugge for the purpose of this trade is an evasion of the Ministry's Order There is also the additional risk that infection might be brought from Belgium, where foot-and-mouth disease is particularly rife at the present time

Treatment of Mentally Defective Child

Dr **VERNON DAVIES** asked the President of the Board of Education if he was aware that Frederick Charles Joyce, now of 65, Heap-street, Oldham, was a mentally defective child with spinal curvature, that his father was killed in action in 1915, that his mother had since died, and that he, his brother, and a sister were living with their mother's sister, Mrs Sparkes, at the above address, which was an ordinary four-roomed house, that Mrs Sparkes's family, consisting of a husband and six children, lived also in this house, one of the children suffering from tuberculosis and another being mentally defective, that for the last two years the War Pensions Committee had been trying to get Frederick Charles Joyce removed from such unsuitable surroundings in vain, that they had been assisted in these attempts by the local education authority, and whether the Board of Education would arrange for the accommodation of this child in an institution —Lord E **PERCY** replied The case of this boy has been already brought to my notice I am making inquiries to see if anything can be done in the direction suggested by my *hon.* friend, and I will let him know the result

Importation of Opium from India

Mr **PONSONBY** asked the Under Secretary of State for the Home Department what amount of opium was sent to this country from India, and for what purposes was it used —Sir W **JOYNSON-HICKS** replied 116,000 lb of raw opium were imported into this country from India in 1925 and 16,000 lb were exported during the same year The Indian opium retained in this country is used for the manufacture of morphine and other drugs and medicinal preparations

Medical Staff of the Ministry of Health

Lieut -Commander **KENWORTHY** asked the Minister of Health if he would give a list of the names of medical men employed by the Ministry other than whole-time staff, and what salaries they received —Mr **NEVILLE CHAMBERLAIN** replied Colonel L W Harrison is the only part-time member of the medical staff of the Ministry His salary is £1500 a year Medical men are employed by the department from time to time, as occasion requires, as part-time referees, to assist the Regional Medical Staff in dealing with cases of insured persons referred by approved societies for examination and advice as to incapacity for work They receive no appointment, salary, or guarantee of employment, and are remunerated by a fee of two guineas for each session

Illness among Junior O T C Members

Mr **RENNIE SMITH** asked the Secretary of State for War what was the illness which prevented 3660 members of the junior division of the Officers' Training Corps from attending camp last year, and whether it was the same cause which kept away large number in the preceding years —Sir L **WORTHINGTON-EVANS** replied Such information as is available goes to show that the epidemics in question were principally mumps and German measles, and that the same diseases were responsible for preventing a large number of

Notes, Comments, and Abstracts.

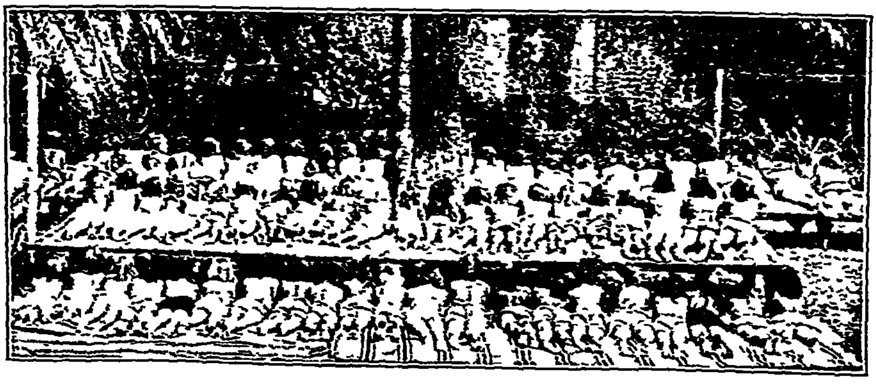
THE TREATMENT OF SURGICAL TUBERCULOSIS

AT THE INSTITUTION OF SANTA MARIA.

By W H Battle, F R C S Eng,
CONSULTING SURGEON, ST THOMAS'S HOSPITAL.

A recent visit to Cannes has given me an opportunity of seeing the treatment of surgical tuberculosis by exposure to the sun, combined with sea bathing, as carried out by Dr A. Pascal at the Institution of Santa Maria in that city This establishment is the first of the kind to be set up in any part of the world and dates from 1903-04

It was founded by Dr. Pascal and is carried on by him almost entirely at his own expense with the aid of several sisters of charity, who take charge of the domestic arrangements and training of the inmates All the patients are females. They are sent by public bodies from various parts of France—even from Paris—and kept until the age of 16, although for a long time there may have been no evidence of tubercle The cases are mostly examples of tuberculous affections of the glands skin bones and joints Girls affected by tuberculosis of the lungs either as the primary disease or as a complication are ineligible. At the time of my visit there was a case of tubercle of the peritoneum under treatment which had responded so well that the abdominal conditions appeared to have become quite normal.



The Home at Santa Maria Lying in the sun.

The establishment is on the outskirts of the town, on the shore of the Gulf de Napoule, an access to the sea at any time being assured by means of a private roadway which passes under the railway line and road. This is an important feature, for it eliminates the danger of injury to the patients who are about 200 in number and would be difficult to shepherd across any road where traffic was permitted

The grounds are divided into two parts, the one nearer the main building containing garden and playing grouned, with some wooden buildings at the sides which are used as class-rooms when the weather is too wet or the sun too hot. There is plenty of air in these rooms as the garden sides are open. The largest of them is on the right hand facing the sea, and this is used as the main dining room, where the meals are served directly from the kitchen. Some distance beyond this and less protected by the trees is an enclosure in which are sloping benches, on which lie rows of girls lightly clothed and in full exposure to the sun and air There is usually no covering to this section of the grounds but arrangements are made to draw blinds across which take away the more intense action of sun during the hotter days of the summer, when the heat might be too great for the patients.

The sleeping apartments are large and well ventilated, and it was pleasant to see how extremely clean everything was kept Each child is supplied on admission with the necessary garments, and these are placed in a cupboard which bears her name and is separated from adjoining ones These cupboards are outside the wards Near them are the lavatories one feature of which is a long trough in which the patients wash their feet before retiring for the night

For six months the new arrivals are made to keep their shoes on during the day, but are gradually induced to do without them so that after this period they join the others, who never wear any foot covering and do not appear to want it The soles of their feet have become quite impervious to pebbles or other hard objects, and they run about without fear of injury

When I paid my visit about 12 o clock on a February day, after an inspection of the patients, especially those who had been admitted for the more serious joint or bone lesions, the family was called upon to go for the daily dip in the sea This was a very interesting part of the treatment, which appeared to be much enjoyed by most of them a few of the more recent younger inmates of the home being, perhaps less vigorous in their expressions of pleasure The parade was under the eye of Dr Pascal who lives on the spot, and a sister; to make more sure of freedom from danger, each of the smaller children is placed under the charge of a senior After the bathe comes manual drill for a few minutes and then the midday meal; as one of the rules of the establishment is the provision of good food, it was not surprising to find the tables fill rapidly when the word was given to sit down. The meal was served hot and passed directly from the kitchen where several of the senior patients assisted whilst others waited on them at the table. They were a happy looking party, full of energy. All who had been residents for some time were well browned, and their muscular system in hard excellent condition.

Operations are not done for the tuberculous lesion, but are sometimes required for deformities resulting from the disease, they are seldom needed A theatre constructed on modern lines was under construction, and a small sterilising plant installed. The usual surgical instruments were already provided by Dr Pascal. It is very interesting to note the absence of splints and rigid apparatus for fixing joints, the spinal cases were none of them in jackets

The experiences of the past few years having shown that a certain number of the inmates became slack and lose flesh during the summer months, Dr Pascal has procured a small estate in the mountains not far from Glasse, to which they are taken. This is used as an auxiliary to the main institution, and from it the family is supplied with vegetables, fruit, milk, and eggs A few weeks in this more stimulating air appears very beneficial, and the natural vigour is restored.

During the whole time of their residence the inmates are undergoing training in various subjects according to their age; the younger ones are taught to read and write, to play games, and to look after their clothes Needlework, housework, cooking waiting at table, gardening, are added, until, at the time of leaving "their home," they are ready for any form of domestic service. It is truly a very interesting sight to see rows of scantily clad patients lying in the sun, toasting their young bodies until quite bronzed by its rays, and during my whole visit I did not see a single patient who looked otherwise than happy Not one appeared to find any inconvenience in lying on the wooden benches, and there were but few still using the invalid chairs because it was still inadvisable to move them

There is no doubt that this institution is doing good work; this was shown by the report published in 1914 and probably another will be issued in a few months giving fuller particulars than I can offer now It can, however, be said that everything I saw showed the value of this method of treatment, especially when it can be carried out in the surroundings and climate of the Institution of Santa Maria. And it may be added that the devotion of Dr Pascal, and his interest in "the family" is worthy of the best traditions of the medical profession

A NEW PURGATIVE

Dr Max Einhorn and Dr H. A. Rafsky writing in the *Journal of the American Medical Association* (June 5th), report on the use of isacen in a series of 47 cases. (An account of the chemical constitution of this drug appeared in The Lancet of July 17th (p 128) under the heading of Analytical Records.) The patients treated were inmates of an institution all 47 were more or less chronic invalids and were over 60 years old Tablets containing 0 005 g were given two three or four times daily and in 39 cases nothing else was needed to keep the bowels tolerably regular In the other cases an enema or

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W

Monday, July 26th, to Saturday, July 31st —Special afternoon demonstration in Clinical Ophthalmology at the Royal Eye Hospital St George's Circus, S E on July 30th, at 3 P M, by Mr Dorrell Open to all members of the medical profession, without fee —North-East London Post Graduate College, Prince of Wales's General Hospital, Tottenham Intensive Course in Medicine Surgery and the Specialties Daily, 10 30 to 5 30 P M Clinical and laboratory methods, demonstrations, operations, general hospital clinics, and formal lectures at 4 30 P M Open to members of the Fellowship of Medicine —West End Hospital for Nervous Diseases, 73, Welbeck-street, W A series of lectures, including clinical demonstrations on selected cases, on the diagnosis and treatment of common diseases of the nervous system Daily, 5 P M, Monday to Friday inclusive Further information from the Secretary of the Fellowship

NORTH-EAST LONDON POST GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N

Special Vacation Course from July 26th to July 31st Second week Daily, to Friday, 10 30 A M to 12 45 P M, Demonstration of Clinical and "Side room" Methods 2 to 2 45 P M, Demonstration of Groups of Clinical Cases 2 30 P M onwards, General Hospital Work, Clinics, Operations &c Clinical Lectures

Monday —3 P M to 4 30 P M, Colonel L W Harrison The Diagnosis and Treatment of Syphilis (cinematograph demonstration)

Tuesday —4 30 P M, Mr T H C Benians Septicæmia

Wednesday —4 30 P M, Mr A E Giles The Treatment of Uterine Fibroids

Thursday —4 30 P M, Mr W Ibbotson Laryngeal Spasm, its Causes and Treatment

Friday —4 30 P M, Mr H W Carson The "Chronic Appendix"

Saturday —11 A M, Dr J K C Laing Demonstration of Typical Cases of Mental Disease (at the Colney Hatch Mental Hospital, New Southgate, N)

Appointments.

Howell, B Whitchurch, F R C S Eng has been appointed Surgeon to the Cheyne Hospital for Children, Cheyne Walk, S W

Johnstone, Robert William, F R C S Edin, M R C P Edin, Professor of Midwifery and the Diseases of Women in the University of Edinburgh

Martin, J Purdon, M D, B Ch Belf, M R C P Lond, Physician at the Dreadnought Hospital Greenwich

Penman, G P, M B, B Ch, F R C S, Second Ophthalmic Surgeon to the Royal Northern Hospital

Whitelocke, Hugh A B, M Ch Oxf, F R C S Eng & Edin, Hon Surgeon, Radcliffe Infirmary, Oxford

St John's Hospital for Diseases of the Skin Wigley, J E M, M B, B S Melb, M R C P Lond, and Dowling, G B, M D Lond, M R C P Lond, Honorary Assistant Physicians

Victoria University of Manchester Ollerenshaw, Robert, M D Manch, F R C S Eng, Honorary Clinical Lecturer in Orthopædics, Bailey, K V M D Manch, Demonstrator in Obstetrics, Brunton, C E, M D Dub, Demonstrator in Human Physiology

Certifying Surgeons under the Factory and Workshop Acts Cartledge, N E D, L R C P Lond, M R C S (E Dereham), Stephens, J B, L R C P Lond, M R C S (Sutton), McAlister, J G, M B, Ch B Glasg (Kilmarnock)

Vacancies.
